PHYSICAL CONSTANTS

Compiled by F. E. SHEIBLEY, Ph.D.

Names of the compounds in the table below are arranged alphabetically. No compound is listed more than once in the table and each compound is given a number.

Synonyms. At the bottom of each page is an alphabetical listing of names for compounds which are to be found in the main body of the table but under a different name; the number following the name refers to the numerical place of this compound in the table; thus, *acetyl-benzoyl-aconine 3* indicates that this compound is the 3d compound in the table where it will be found listed under the name *aconitine*.

Appearance. In addition to the crystalline form and color, the solvent used in purification is often given; thus, "rhomb./al." indicates that rhombic crystals were obtained when the compound was crystallized from alcohol.

Optical Properties are given in the column headed "[*a*]"; only the directions of the specific rotations have been indicated, since the factors affecting the determination of this property are too variable to come within the scope of the table.

Color Reactions with Sulfuric Acid, where available, have been included as an

Abbreviations used in the table

a., acid
abs., absolute
ac. a., acetic acid
act., acetone
al., alcohol
alk., alkali (i. e. aqueous NaOH or KOH)
am. al., amyl alcohol
amor., amorphous
anh., anhydrous
aq., aqueous; water
bl., blue
B. P., boiling point
br., brown
bz., benzene, C_6H_6
c., cold
chl., chloroform, $CHCl_3$
colorl., colorless
cryst., crystals or crystalline
d, dextro-rotatory
d., decomposes or decomposition
deliq., deliquescent
dil., dilute
dk., dark
diss., dissociates
effl., efflorescent
et., ether $(C_2H_5)_2O$
Et, ethyl (C_2H_5)
EtOAc, ethyl acetate
gly., glycerol
grn., green
h., hot
hex., hexagonal
hyg., hygroscopic
i., insoluble
in., inactive
l, levo-rotatory
leaf., leaflets or leaves

No.	Name	[a]	Formula	Appearance	Melting Point °C.

5	hydrobromide	...	$C_{34}H_{47}O_{11}N \cdot HBr \cdot \frac{1}{2}H_2O$	need./al.	206–7
6	hydrochloride	*l*	$C_{34}H_{47}O_{11}N \cdot HCl \cdot 3H_2O$	cryst.	149; 170*
7	**Adenine**	...	$C_5H_5N_5$	need. + $3H_2O$/aq.	360–5 d. subl. 220
8	**Agmatine**	...	$HN:C(NH_2) \cdot NH \cdot (CH_2)_4NH_2$	.....	.....

* Melting point of the anhydrous compound.

OF ALKALOIDS

aid in the making of rapid preliminary examinations.

Solubilities expressed by numbers are given in parts by weight of solvent required to dissolve one part of the alkaloid at a temperature of approximately 25°C. Because of the wide discrepancies existing between many of these figures as found in the literature no claim to accuracy can be made, and the values stated are perhaps best considered as upper limits.

References. The information given in the table has been collected mainly from the following sources:

Henry: **Plant Alkaloids,** 3d edition. Published by J. and A. Churchill, London (1939).

Merck's Index, 5th edition. Published by Merck and Co., Inc., Rahway, N. J. (1940).

Heilbron: **Dictionary of Organic Compounds.** Published by Oxford University Press, New York (1934).

Beilstein: **Handbuch der Organischen Chemie,** 3d edition.

PHYSICAL CONSTANTS

Compiled by F. E. SHEIBLEY, Ph.D.

Names of the compounds in the table below are arranged alphabetically.

Appearance. In addition to the crystalline form and color, the solvent used in purification is often given; thus, "rhomb./al." indicates that rhombic crystals were obtained when the compound was crystallized from alcohol.

Optical Properties. These are indicated by the symbols *d*, *l*, or *in.* following the name. Most of the optically active glucosides are levo-rotatory.

Solubilities. Most glucosides are soluble in cold or hot water. The solubilities given for alcohol refer to the ordinary alcohol of approximately 95% concentration. Solubilities expressed by numbers are given in parts by weight of solvent required to dissolve one part of the glucoside. Because of discrepancies existing between many of these figures as found in the literature no claim to accuracy can be made,

Abbreviations used in the table

a., acid
abs., absolute
ac., a., acetic acid
act., acetone
al., alcohol
alk., alkali (i. e. aqueous NaOH or KOH)
amor., amorphous
anh., anhydrous
aq., aqueous; water
br., brown
bz., benzene, C_6H_6
c., cold
Chl., chloroform, $CHCl_3$
colorl., colorless
conc., concentrated
cryst., crystals or crystalline
crystn., crystallization
d., decomposes or decomposition
d, dextro-rotatory
dil., dilute
et., ether $(C_2H_5)_2O$
EtOAc, ethyl acetate
h., hot
hyd., hydrate
hyg., hygroscopic

No.	Name	Formula	Appearance	Melting Point °C.

Aurantiin 49

OF GLUCOSIDES

and the numerical values stated are perhaps best considered as upper limits.

Hydrolytic Products. By hydrolysis glucosides are split into a sugar (generally glucose) or a mixture of sugars, and a principle characteristic of the glucoside. The hydrolysis is usually effected with hot dilute sulfuric acid or hydrochloric acid, and less often with emulsin or baryta water.

References. The information given in the table has been collected mainly from the following sources:—

PROPERTIES

Compiled by

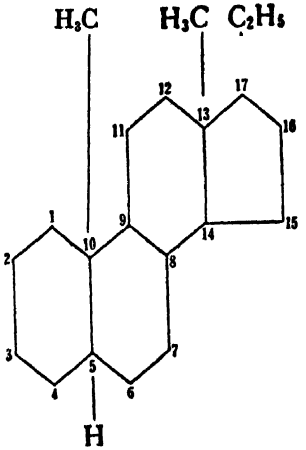
Perhydrocyclopentenophenanthrene skeleton

Estrane $C_{18}H_{30}$
Parent substance of estrogenic hormones

Abbreviations used in the table:

a., acid	app., approximately	et., ether	sl., slightly	vol., volatile
alk., alkali	aq., water	i., insoluble	solv., solvent	
al., alcohol	compd., compound	s., soluble	veg., vegetable	

UNITS. When first isolated from natural materials, steroid hormones were measured by their biological functions and expressed in functional units. For a number of reasons, among which are isomerism, methods of extraction, methods of administration, type of solvent, number of doses, species difference and particularly because of individual biological vagary, comparatively few investigators agreed on the number of units to which a given weight of hormone was equivalent. Expression in milligrams of pure substance was a later development, particularly after syntheses and analytical methods had been perfected. There is no difference of opinion regarding units by definition but only regarding units as a result of experimental work. Presently (1955), the potency of nearly all hormones is expressed in terms of weight, in milligrams. Among reasons for this advance is the synthetic preparation of hormones and the high purity of the manufactured products.



EQUIVALENTS IN UNITS OF 1 MILLIGRAM QUANTITIES

Androsterone	10 CU	(*a*; *j*)	Estrone	2,666 RU	(*c*; *p*)
Benzestrol	25,000 IU	(*b*)	Estrone	1,000 RU	(*c*; *k*; *q*)

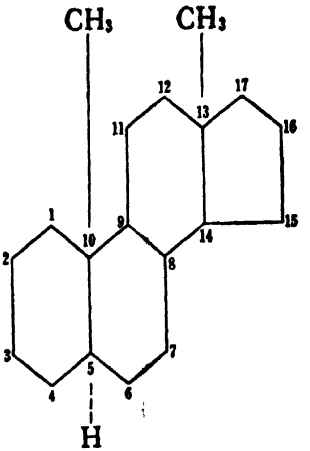
Estrone	10,000 IU	(*b*; *j*)			



(*a*) Capon Units of androgenic potency; (*b*) International Units of estrogenic potency or Estrone Units; (*c*) Rat Units of estrogenic potency by Allen-Doisy method; (*d*) International Benzoate Units of estrogenic potency; (*e*) International Units of insulin activity; (*f*) International Units of progestational activity; (*g*) Corner-Allen Units; (*h*) Clauberg Rabbit Units; (*i*) European Clinical Units; (*j*) by definition; (*k*) by calculation; (*m*) by experimental finding; (*n*) for oral use only; (*p*) chemical determination, *J. Biol. Chem.* 116, *415* (*1936*); (*q*) conversion data unreliable.

OF HORMONES

ERWIN DI CYAN, Ph.D.

Pregnane $C_{21}H_{36}$
(17(α)-ethyl-etiocholane)
Parent substance of progestational and cortical hormones

Androstane $C_{19}H_{32}$
(etio-allo-cholane)
Parent substance of androgenic hormones

FORMULAS AND NOMENCLATURE

Frequently, structural skeletons of hormones are shown with a bond going upward from the carbon atom at position 10 and/or 13 but no methyl group (CH_3) appears. In these instances, the CH_3 group (designated the angular methyl group) is understood to be present and its omission from the formula merely follows a convention of allowing a bond to stand for this group. The formula for estrane on the previous page shows the angular CH_3 group in position 13. The formulas above for pregnane and androstane show the angular CH_3 groups in positions 10 *and* 13. Chemical names of steroid hormones (in contradistinction to official or trivial names) are usually indicative of their structure. Often the chemical names of two hormones may differ only by a prefix and/or a suffix, and a number indicating the location of a group on the ring. Prefixes and suffixes such as keto, ol, one, etc., have the same meanings as in the nomenclature of other organic compounds (see section on Organic Chemical Nomenclature). In the naming of hormones, the Greek α indicates a group above and a group below the plane of the molecule (*trans*); β indicates both groups either *above* or *below* (*cis*). The prefix **allo** bears the same relationship to isomers as the term sibbling bears to brother and sister, and can refer to any one of two isomers. **Dehydro** is used to show the loss of two hydrogens from the parent substance; **dihydro** indicates a gain of two hydrogens. **Desoxy** is used to show the loss of one oxygen atom from the parent substance. The prefix **epi** is used with an isomer which differs from its fellow by a change in the constellation around one carbon atom. The prefix **etio** indicates the last product of a degregation which still bears a fundamental resemblance to the original and, if further degraded, gives a substance with little or no resemblance to the parent. The term **oxo** indicates a ketone (carbonyl) group. The prefix **iso** is used to show an isomeric relationship.

No.	Name	Source	Synonym	Formula; mol. wt.
	Acetoxypregnenolone Δ^5-pregnene-3(β), 21-diol-20-one 21-monoacetate.	Synthetic from cholesterol or sapogenins.	21-acetoxypregnenolone.	$C_{23}H_{34}O_4$ 374.50
	Androsterone androstan-3(α)-ol-17-one; 3-hydroxy-androstan-17-one.	Synthetic from cholesterol; from male urine.	*cis*-androsterone.	$C_{19}H_{30}O_2$ 290.43
	Corticosterone 17(β)-[1-keto-2-hydroxy-ethyl]-Δ^4-androstene-3-one-11(β)-ol.	From adrenal cortex; from urine.	11, 21-dihydroxyprogesterone; Kendall's "Compd. B"; Reichstein's "Compd. H."	$C_{21}H_{30}O_4$ 346.45
	Cortisone 17-hydroxy-11-dehydrocorticosterone; 17 (α)-[1-keto-2-hydroxy-ethyl]-Δ^4-androstene-3, 11-dione-17-(β)-ol.	Adrenals; synthetic.	Kendall's "Compound E"; Wintersteiner's "Compound F."	$C_{21}H_{28}O_5$ 360.43
	Dehydroi sterone Δ^5-androsten-3(β)-ol-17-one; Δ^5-androstene-3-(β)-ol-17-one.	Synthetic from cholesterol; from male urine.	*trans*-dehydroandrosterone; dehydro-*iso*-androsterone; dehydroandrosterone.	$C_{19}H_{28}O_2$ 288.41
	Desoxycorticosterone 17(α)-[1-keto-2-hydroxy-ethyl]-Δ^4-androstene-3-one; Δ^4-pregnene-21-ol-3,20-dione; Δ^4-21-hydroxy-pregnene-3,20-dione.	Synthetic.	11-desoxycorticosterone; 21-hydroxyprogesterone; 21-oxyprogesterone; deoxycorticosterone; deoxycostone.	$C_{21}H_{30}O_3$ 330.45
	Desoxycorticosterone acetate 11-desoxycorticosterone-21-acetate; see also desoxycorticosterone.	Synthetic.	deoxycostone acetate; see also desoxycorticosterone.	$C_{23}H_{32}O_4$ 372.49
	Dihydroandrosterone 3-*cis*-17-*trans*-androstandiol.	Synthetic from cholesterol.	androstandiol.	$C_{19}H_{32}O_2$ 292.45

OF HORMONES

No.	Melting point °C	$[\alpha]^{25}D$	Solubility	Method of testing	Use and method of administration
1	184-5	+37-+43 in dioxane at 20°.	aq.-i.; vol. solv.-s.; veg. oils-sl.s.	Chemical: light br. color with tetra-nitro-methane.	Experimentally in treatment of arthritis.
2	185-185.5	+86-+90 1% in dioxane.	aq.-i.; vol. solv.-s.; veg. oils-sl.s.	Biological: increase in size of capon comb; increase in weight of seminal vesicles	Excretion product of testosterone which supplanted it, and which is app. 10 times as active; for uses, see testosterone and testosterone propionate.
3	180-182	+222 1% in al.	aq.-sl.s.; vol. solv.-s.; veg. oils-sl.s.	Biological.	In shock, by intramuscular or subcutaneous injection of aq. or oil solution; of the adrenal hormones, desoxycorticosterone acetate is the one most widely used, *q.v.*
4	220-224	+195-+209 (alcohol)	aq.-i.; vol. solv.-s.	Chemical.	Orally or intramuscularly as acetate in rheumatoid arthritis principally, in allergy, in diseases characterized by inflammation, in certain dermatological entities and in adrenal insufficiency as in Addison's disease. (Cf., hydrocortisone.)
5	dimorphic; need., 140-1; leaf., 152-3	+10 in al.	aq.-i.; vol. solv.-s.; veg. oils-sl.s.	Biological: see androsterone.	Excretion product of testosterone (*q.v.*) which supplanted it; for effect see testosterone and testosterone propionate.
6	141-2	+178 in al.	.....	Biological: see desoxycorticosterone acetate.	The acetate of desoxycorticosterone is used therapeutically, *q.v.*
7	154-160	+168-+178 1% in dioxane at 20°.	aq.-i.; vol. solv.-sl.s.; veg. oils-sl.s.	Biological: on adrenalectomized dogs.	In Addison's disease, by intramuscular injection of oil solution, or by subcutaneous implantation of pellets, or sublingually.
8	218-223	+12	aq.-i.; vol. solv.-s.; veg. oils-sl.s.	Biological: see androsterone.	Rarely used; for effect see testosterone and testosterone propionate.

No.	Name	Source	Synonyms	Formula; mol. wt.
9	**Equilenin** $\Delta^{1,3,5:10,6,8}$-estrapentaene-3-ol-17-one; 3-hydroxy-17-keto-$\Delta^{1,3,5.10,6,8}$-estrapentaene.	Pregnant mares' urine.	.....	$C_{18}H_{18}O_2$ 266.32
10	**Equilin** $\Delta^{1,3,5.10,7}$-estratetraene-3-ol-17-one; 3-hydroxy-17-keto-$\Delta^{1,3,5,7}$-estratetraene.	Pregnant mares' urine.	.....	$C_{18}H_{20}O_2$ 268.34
11	**Estradiol** $\Delta^{1,3,5}$-estratriene-3,17-*trans*-diol; 3-dihydroxy-1,3,5-estratriene; 3,17-dihydroxy-$\Delta^{1,3,5}$-estratriene.	Reduction of estrone; pregnant mares' urine; sows' ovaries.	dihydrotheelin; dihydrofolliculin; dihydroxyestrin; α-estradiol; dihydroestrone.	$C_{18}H_{24}O_2$ 272.37
12	**Estradiol benzoate** 3-benzoxy-$\Delta^{1,3,5}$-estratriene-17-ol; see also estradiol.	Esterification of estradiol.	See also estradiol.	$C_{25}H_{28}O_3$ 376.47
13	**Estriol** $\Delta^{1,3,5:10}$-estratriene-3-16-*cis*-17-*trans*-diol; 3,16,17-trihydroxy-$\Delta^{1,3,5}$-estratriene.	Pregnant mares' urine; placenta.	theelol; destriol; trihydroxyestrin; follicular hormone hydrate.	$C_{18}H_{24}O_3$ 288.37
14	**Estrone** $\Delta^{1,3,5}$-estratriene-3-ol-17-one; 3-hydroxy-17-keto-1,3,5-estratriene.	Pregnant mares' urine.	folliculin; ketohydroxyestrin; theelin	$C_{18}H_{22}O_2$ 270.36

No.	Melting point °C	$[\alpha]^{25}D$	Solubility	Method of testing	Use and method of administration
9	258-259	+89 in dioxane.	aq.-i.; al.-sl.s.; vol. solv.-s.; veg. oils-sl. s.	Biological: see estrone.	A component of natural estrogenic substance; for effect see estrone.
10	238-240	+325 in al.; +308 1% in dioxane.	aq.-i.; vol. solv.-s.; veg. oils-sl.s.	Biological: see estrone.	A component of natural estrogenic substance; for effect see estrone.
11	173-179; stereoisomeric β-estradiol m. 223	+76-+83 1% in dioxane. β-estradiol +53-+56	aq.-i.; vol. solv.-s.; alk.-s.; veg. oils.-sl.s.	Biological: see estrone; also chemical.	See estrone; estradiol is active orally, parenterally and topically.
12	191-196 (174-175)	+58-+63 2% in dioxane.	aq.-i.; vol. solv.-s.; et.-sl.s.; veg. oils-sl. s.	Biological: see estrone; also chemical.	See estrone; estradiol benzoate differs from estradiol or estrone in that its effect is prolonged.
13	282	+58 ± 5 1% in dioxane.	aq.-i.; vol. solv.-s.; veg. oils-sl. s.	Chemical: triacetate deriv. melts at 125-127°. Biological: see estrone.	See estrone; estriol differs from estrone and estradiol benzoate in that it is active orally.
14	258-262	+158-+168 1% in dioxane.	aq.-v.sl.s.; vol. solv.-s.; alk.-s.; al.-s.; veg. oils-sl. s.	Chemical: with 2,4-dinitrophenylhydrazine; colorimetric: Kober reaction with phenolsulfonic acid; spectrographic: see ref. to J. A. Ph. A.	In menopause, female hypogonadism and other gynecological disturbances by intramuscular injection of oil solution or water suspension, subcutaneous implantation of pellets, intravaginal insertion of suppositories or topical application of ointment.
				Biological: cornified cells in vaginal smears of ovariectomized rats, injected with estrone (or estradiol or estradiol benzoate). Estriol and ethinyl estradiol may be tested by same criteria, except that they are not injected, but fed by mouth or stomach tube, since they are used orally.	

No.	Name	Source	Synonyms	Formula; mol. wt.
15	**Estrone benzoate** 3-benzoxy-$\Delta^{1,3,5}$-estratriene-17-one.	Esterification of estrone.	See also estrone.	$C_{25}H_{26}O_3$ 374.46
16	**Ethinyl** or **Ethynyl estradiol** 17-(β)-ethinyl-$\Delta^{1,3,5,10}$-estratriene-3,17(β)-diol; 17-ethinyl-3,17-dihydroxy-$\Delta^{1,3,5}$-estratriene.	Estradiol.	17-ethinyl estradiol; 17-ethynyl estradiol.	$C_{20}H_{24}O_2$ 296.39
17	**Hydrocortisone** 17-hydroxycorticosterone; 17-[1-keto-2-hydroxyethyl]-Δ^4-androstene-11,17-(α)-diol-3-one.	Adrenals: synthetic.	Kendall's "Compd. F"; Reichstein's "Substance M"; 17-oxycorticosterone.	$C_{21}H_{30}O_5$ 362.45
18	**Insulin**	Pancreas.	soluble insulin.	$C_{45}H_{75}O_{17}N_{11}S$ 20,000 to 40,000 (?)
19	**Pregneninolone** Δ^4-17-ethinyl-androsten-17-ol-3-one; 17(β)-ethynyl-Δ^4-androstene-17(α)-ol-3-one.	Synthetic.	pregneninonol; anhydro-hydroxy-progesterone; ethinyl testosterone; ethisterone.	$C_{21}H_{28}O_2$ 312.43
20	**Pregnenolone** Δ^5-pregnene-3(β)-ol-20-one; 17(β)-[1-ketoethyl]-Δ^5-androstene-3(β)-ol.	Testicular tissue; synthetic from cholesterol or sapogenins.	Δ^5-pregnenolone.	$C_{21}H_{32}O_2$ 316.47

No.	Melting point °C	$[\alpha]^{25}D$	Solubility	Method of testing	Use and method of administration
15	220	+120 1% in dioxane.	aq.-i.; vol. solv.-s.; et.-sl.s.; veg. oils-sl. s.	Biological: see estrone.	See estrone; estrone benzoate differs from estradiol or estrone in that its effect is protracted; bears the same relation to estrone as estradiol benzoate bears to estradiol; little used in U. S. A.
16	141-146	+1-+10 1% in dioxane.	aq.-i.; vol. solv.-s.; alk.-s.; veg. oils-sl. s.	Chemical: benzoylated deriv. melts 200-202°. Biological: see estrone.	See estrone; ethinyl estradiol is active orally.
17	217-220	+167 in abs. alcohol.	aq.-sl. s.; glac. acetic a.-s.; dioxane-s.	Chemical.	Orally; topically; parenterally as acetate, in rheumatoid, or intraarticularly in osteoarthritis; in allergy; in many dermatological entities; in diseases characterized by inflammation and in adrenal insufficiency; see cortisone.
18	233	levorotatory.	aq.-s.; al.-s.	Chemical: nitrogen. Biochemical: blood sugar. Biological: lowering blood sugar level in rabbits, inducing hypoglycemic convulsions.	In diabetes mellitus by subcutaneous injection of aqueous solution for rapid effect; by subcutaneous injection of aqueous solution with globin and zinc or protamine and zinc for prolonged effect.
19	266-273	+18-+28 1% in dioxane.	aq.-i.; vol. solv.-sl.s.; veg. oils-sl. s.	Biological: see progesterone.	See progesterone; pregnenmolone is active orally.
20	193	+28-+30 in al. at 20°.	aq.-i.; et.-i.; veg. oils-v. sl.s.; vol. s.-s.	Biological for hormonal effect; chemical for antiarthritic effect.	For spermatogenic effect particularly to mitigate depression of spermatogenesis upon administration of estrogens; recently in treatment of arthritis in which pregnenolone is used intramuscularly and the acetate orally.

For a review of modified natural resins and synthetic resins (ester gums, maleated and limed rosin, phenolated resins, etc.) see (1) for resins and of synthetic resins of interest to the paint, printing ink and allied trades: *Bull. 738* (May, 1950) of Scientific Section of Natl. Paint, Varnish & Lacquer Assoc., Inc.—Resin Index of 1950; (2) for resins of interest to the plastics trade, the latest *Modern Plastics Encyclopedia* published by Plastics Catalogue Corp.

Classification. The 3d column headed "Class," places each resin into one of the following groups:

I. Natural gum-resins of vegetable origin, which contain some resinous constituents in admixture with carbohydrate bodies, so that the resulting complex will yield some water-soluble constituents.

II. Natural resins of animal origin.

III. Natural resins of vegetable origin—largely mixtures of resin acids, alcohols and esters, with some resenes or hydrocarbon bodies. This class is divided into the following groups:

A. Oleo-resins and balsams—very fresh exudations containing volatile solvents which act as carriers.

B. New resins—same as IIIA—with the solvents gone completely.

Name	Source	Class	Sp. Gr.
Gum Accroides Used to color spirit varnishes and nitrocellulose lacquers, and in sealing wax. Composition is 85% p-coumaric ester of xanthoresinotannol.	A species of *Xanthorroea* in Australia — Yellow variety	III. B	.....
	Red variety	III. B	.....
Accra Copal	W. Africa	III. C	1.033
Amber Used in jewelry; it is the hardest and most highly fossilized resin. Composition is 28% succino-abietic acid, 70% esters of succinic acid and succino-resinol.	Baltic coast and Burma. Fossil resin from extinct conifers	III. D	1.052 (1.05-1.11)
Gum Ammoniacum Composition:—20-26% gum, 65-75% resin, balance water, ash, etc.	*Dorema Ammoniacum*, from Persia and Africa	I.	1.19-1.21
Red Angola Copal Commonly used in Europe; less in in U. S. A.	Semi-fossil from Angola, W. Africa	III. C	1.066-1.068
White Angola Copal	W. Africa	III. C	1.055
Gum Arabic (Acacia) Used in adhesives and emulsions. Varieties:—gum senegal, kordofan.	Dried juice from bark of *Acacia senegal*	True gum	.....
Asafoetida Composition:—25% gum, 60% resin ester, 7% essential oil. U. S. P. requires ash to be under 10%. Used in treatment of heaves.	Species of *Ferula*	I.	.....
Batu An important variety of East India resin (*q.v.*).			

C. Semi-fossil resins—the products of the action of the elements on new resins over a relatively short time. These resins are not entirely soluble unless melted and partially depolymerized.

D. Fossil resins—those exposed for long periods of time. They are substantially insoluble.

IV. Natural hydrocarbon resins.

The 4th column gives the **specific gravity**, the 5th gives the **softening point (S. P.)**, and the 6th gives the **melting point (M. P.)**. The next three columns give the **acid, saponification,** and **iodine numbers** in that order. Figures enclosed in parentheses indicate the extreme values reported by different investigators. The 10th and last column gives the solubility of the resins in various solvents. The figures 1 to 12 refer to the following solvents: 1-ethyl alcohol; 2-methyl alcohol; 3-ether; 4-benzene; 5-acetone; 6-amyl alcohol; 7-chloroform; 8-aniline; 9-benzaldehyde; 10-carbon tetrachloride; 11-turpentine; 12-amyl acetate. The letter "s." (soluble), indicates that over 90% of the resin is soluble in the solvents numbered there-after; "p. s." (partly soluble), indicates that from 41-90% of the resin will dissolve, while "i." (insoluble), indicates that 40% or less dissolves. The **ester number** is indicated by **E,** and the methoxyl number by **M.**

Name	Source	Class	Sp. Gr.
Benguela Copal An uncommon resin.	W. Africa	III. C	1.058 (1.035-1.062)
Gum Benzoin Composition:—69% cinnamic acid esters, 30% cinnamic acid, 1% or less of vanillin.	Sumatra and Siam *Styrax Benzoin*	III. A, B	1.063-1.092
Brazil Copal	S. America *Hymenae courbaril*	III. C	1.053
Cameron Copal	W. Africa	III. C	1.052
Canada Balsam Used in optometric work.	*Abies balsamea*	III. A	0.90
Coal Resin A dark colored natural hydrocarbon resin	Utah coal	IV.	1.03
Colombia Copal	S. America	III. C	1.054
Congo Copal Composition:—89% resin acids, 8.5% resenes. It is the commonest fossil varnish resin, widely used because of its low price. Loango copal is a variety of Congo.	Belgian Congo	III. C	1.061
Copaiba Balsam Oleo resin, named, as are many others, from port of shipment. Used in medicine.	S. American species of *Copaiba*	III. A	0.916-0.995
Dammar A common resin, used in varnish and lacquer. It is dissolved in coal tar solvents and alcohol, which precipitate incompatible ingredients.	East Indian trees of *Shorea* variety	III. B	1.031 (1.031-1.123)
Demerara Copal Semi fossil gum. Not in common use.	British Guiana	III. D	1.047
Dragon's Blood Used as red coloring agent.	E. Indies (Sumatra) *Calamus draco*	III. A, B	1.25
East India A very common resin, widely used in the varnish industry. Composition:—12% resin acids, 78% resenes.	Species of *Dipterocarpus* in East Indies	III. B, C	.....
Gum Elemi Contains some essential oils, mixed with resins. Used in lacquers and spirit varnishes.	Mainly from the Philippines; *Canarium commune*	III. A, B	1.018-1.083

Name	Source	Class	Sp. Gr.
Galbanum Composition:—64% alcohol-soluble resin, 27% gum, 9% essential oil. Used in medicine.	*Ferula galbaniflua*	I.	1.109-1.133
Gamboge Composition:—65-75% resin, 20-25% gum. Used as a yellow coloring agent and as a purgative.	Siam. *Garcinia Hanburii*	I.	.....
Gilsonite A natural, dark, asphaltic resin.	Mineral deposits	IV.	1.015
Guaiacum Used in medicine.	From wood of *Guajacum officinale* and *G. sanctum*	III. B	.....
Gurjun Balsam	Java and Cochin, China *Dipterocarpus*	III. A	0.960-0.966
Jalap, Resin of Used in medicine; purgative.	*Exogonium jalapa*	III. B	.. ..
Karaya Gum (Indian gum) Resembles tragacanth. Used in hair "wave set" and in foods.	India; Africa *Sterculia urens*	I.	1.461-1.480
Kauri, Bush Composition:—64.5% resin acids, 12% resenes.	A recent to semi-fossil variety of Kauri. It is the softest grade of Kauri on the market.	III. B, C	1.030-1.038
Kauri, Fossil Composition:—69% resin acids, 9.5% resenes. A common resin used for high grade varnishes.	*Agathis australis* (the New Zealand Kauri Pine)	III. C, D	1.053
Kissel Copal Said to make poor varnishes.	Africa	III. C	1.066
Gum Lac (Shellac) (Data given is for orange shellac.)	Secretion of *Coccus lacca*, the lac insect	II.	1.182 (1.113-1.214)
Madagascar Copal A hard fossil resin, used little because of its high price.	Fossil gum from Madagascar	III. D	1.056
Manila, Soft Used as a cheap shellac substitute in spirit varnishes.	E. Indies. Trees of *Hymenea* group	III. B	1.060
Manila, Hard The hardest grade used in the varnishes. A very common resin.	E. Indies	III. C	1.065

Name	Source	Class	Sp. Gr.
Mastic Formerly much used in lacquers and spirit varnishes. Not so popular now.	Evergreen shrubs in Mediterranean regions. *Pistacia lentiscus*	III. B	1.057 (1.04-1.07)
Mecca Balsam (Balm of Gilead) Used as a tonic in the Orient.	*Balsamodendron gileadense* in Arabia	III. A	.....
Myrrh (Bdellium is a variety.) Has 50-60% gum. Used in medicine.	Turkey, India, Arabia, Somaliland. Species of *Comniphora*	I.	.....
Peru Balsam Has 55-66% cinnamein. Used in medicine and perfumery.	Central America. Black liquid from *Toluifera pereirae*	III. A	1.14-1.151
Olibanum or **Frankincense** Used in perfumery.	*Boswellia Carterii*, etc. Somaliland and S. Australia	I.	.....
Pontianak Composition:—84.5% resin acids, 4% resenes. A recent to semi-fossil resin. Similar to, but harder and less odorous than soft manila. Used in spirit varnishes.	Borneo	III. B, C	1.037
Rosin or **Colophony** Largely abietic acid, $C_{20}H_{30}O_2$. Commonest and cheapest resin. Graded according to color. Used in paints, soap, paper, etc.	*Pinus* species. Mostly *Pinus palustris*. Gum obtained on distillation	III. B	1.045-1.086
Gum Sandarac Composition:—85% sandaracolic acid, 10% callitrolic acid. Common resin for use in spirit varnishes.	N. E. Africa. Small trees: *Callitris quadrivalvis*	III. B	1.073
Sierra Leone Copal The hardest of the recent resins.	W. Africa. *Guibourtia Copalifera*	III. B	1.072
Balsam Storax Used in medicine.	Levant and Greece. *Styrax officinalis*	III. A	.....
Balsam Tolu	S. America. *Toluifera balsamum*	III. A	.....
Gum Thus A soft, fresh oleoresin from slashed trees, yielding turpentine and rosin on distillation.	*Pinus* species	III. A	.....
Gum Tragacanth Swells in water—used in adhesives.	Asia Minor and Persia. *Astragalus gummifer*	Gum	.....

Venice Turpentine	European larch. *Larix europaea*	III. A	1.094-1.190
Zanzibar Copal Composition:—85% resin acids, 10% essential oils, 5% resenes. A common resin, little used only because of its high price. Soluble in oils after depolymerization.	Zanzibar and E. Africa *Trachylobium verrucosum*	III. D	1.054-1.063

GLYCERIDE CONTENT OF DRYING OILS

The values in the table give the percentage content of various fatty acid esters present in the glyceride structure of the common drying oils.

The composition of different samples of the same drying oil may vary considerably. These variations are often reflected in changes in the constants of the oil, particularly the iodine value.

COMPOSITION AND

See also special tables on

Proteins contain the elements of carbon, oxygen, hydrogen, nitrogen and often among others sulfur and phosphorus, thus furnishing the elements for the building and repairing of tissue as well as energy for heat and muscular power. They are supplied by vegetable proteins—grain foods, legumes and nuts, and animal proteins—flesh foods, eggs and dairy products. **Fats** contain the elements of carbon, hydrogen and oxygen and are utilized for heat and muscular power; the excess is stored as fat in the body. The sources of this type of food are the vegetable and animal fats or oils. **Carbohydrates** contain the elements of carbon, hydrogen and oxygen; they furnish fuel for heat and muscular energy. The excess is transformed and stored in the body as fat. **Water** contains the elements oxygen and hydrogen and is a neutral substance which does not furnish energy but is necessary for the digestive fluids, for transporting soluble substances in the blood and lymph, for maintaining proper dilution of soluble substances in the body, for excreting soluble wastes and for regulating the temperature of the body. It is furnished by fluids taken (water, beverages, soups, etc.), by the water content of solid foods and by that formed in metabolism. **Mineral salts** share in forming and maintaining bones, teeth, blood, etc., and aid in digestion and metabolism. Among such minerals are the following elements. **Aluminum** occurs only in traces and is probably of very little importance. **Arsenic** is an acid forming element occurring in traces in many animal and vegetable foods; it is probably of very little importance. **Calcium**, a base forming element, is a sinew, muscle, and blood mineral and maintains the bone structure. It is supplied by watercress, turnip tops, dandelions, spinach, lettuce, tomatoes, lemons, oranges, strawberries, cranberries, cheese, milk, buttermilk, wheat, oats, rye, barley, peas, lentils, and nuts. **Chlorine**, an acid forming element, is a secretion mineral. The amount required per day is 6 to 8 grams. It is supplied by table salt, lettuce, spinach, cabbage, beets, parsnips, milk, cheese, strawberries, bananas, pineapples, grapes, potatoes, beans, barley, corn, oats, peas, and sea foods. **Fluorine**, an acid forming element, furnishes a substance needed in building tooth enamel and eye tissue. It is supplied in minute amounts by vegetables, fruits, eggs, milk and seeds. **Iodine**, an acid forming element, is a gland mineral. It is supplied by iodized salt, salt water fish, asparagus, cabbage, green peas, beans, rice, potatoes, lettuce, mushrooms, tomatoes, grapes, pears, and pineapples. **Iron** is a blood mineral occurring in the red blood cells. It is supplied by

USE OF FOODS

Vitamins, and Fats and Oils.

lettuce, spinach, turnips, asparagus, leeks, onions, cabbage, lentils, radishes, pumpkin, oats, rice, rye, beans, mushrooms, grapes, raisins, strawberries, gooseberries, cherries, prunes, grapefruit, pineapple, currants, and almonds. **Magnesium**, a base forming element and a cell-building substance, maintains chiefly teeth, bone and muscular tissue. The amount required per day is the equivalent of 0.3 to 0.5 grams magnesium oxide (MgO). It is supplied by dandelions, lettuce, watercress, turnip tops, cabbage, celery, asparagus, tomatoes, berries, lemons, bananas, oranges, limes, pineapple, raisins, almonds, walnuts, wheat, oats, rice, and barley. **Phosphorus** is an acid forming element which is necessary for the building of nervous tissue, bones, and teeth. It is supplied by eggs, milk, sea foods, liver, asparagus, watercress, turnips, beans, lentils, figs, prunes, currants, apples, berries, wheat, oats, barley, rice, and rye. **Potassium** is a strongly basic element helping to make the tissues elastic. The amount required per day is the equivalent of 2 to 3 grams of the oxide (K_2O). It is supplied by potato skins, spinach, beans, turnips, parsnips, lettuce, tomatoes, rhubarb, huckleberries, limes, and lemons. **Silicon**, an acid forming element, supplies a substance necessary for building hair, nails, skin, and teeth. It is supplied by egg whites, meat, nuts, lettuce, dandelions, asparagus, onions, radishes, cucumbers, celery, strawberries, apples, apricots, cherries, prunes, mushrooms, olives, oats, rye, and millet. **Sodium**, a strongly basic element, aids digestion and is a blood and gland mineral. The amount required per day is the equivalent of 4 to 6 grams of the oxide (Na_2O). It is supplied by table salt, spinach, dandelions, cabbage, beets, cauliflower, asparagus, carrots, cucumbers, turnips, strawberries, figs, prunes, apricots, olives, tomatoes and milk. **Sulfur** is an acid element utilized in building protein tissue. The amount required per day is the equivalent of 2 to 3.5 grams of the oxide (SO_3). It is supplied by eggs, cabbage, meats, fish, corn, cheese, brussels sprouts, string beans, lima beans, raspberries, cranberries, and raisins. **Manganese** is a tissue mineral and aids in carrying oxygen from the lungs to the cells. It is supplied by endive, watercress, parsley, almonds, walnuts, and egg yolks.

[1] Allowances must be adjusted to meet specific needs. The proper allowance is that which over an extended period will maintain body weight or growth at the level most conducive to well-being.

[2] Allowance depends on relative amounts of vitamin A and carotene. Values in the table are based on the premise that approximately two-thirds of the vitamin A is contributed by carotene and that carotene has half or less than half the value of vitamin A.

[3] For adults (except pregnant and lactating women) receiving 2000 calories or less, the allowances of thiamin and niacin may be 1 mg and 10 mg respectively. Other members of the B complex also are required, though no values can be given. Foods with adequate thiamin, riboflavin, and niacin will tend to supply sufficient of remaining B vitamins.

[4] Male adults need relatively little. The need will usually be provided for if the diet is satisfactory in other respects.

[5] Vigorous adults leading a normal life need no supplemental amounts. Ingestion of small supplemental amounts is desirable for persons shielded from sunlight and for elderly persons.

[6] For pregnant, sedentary women. During the latter part of pregnancy a 20% increase is recommended.

[7] Allowances are based on needs for the middle year (2, 5, 8, etc.), for moderate activity, and for average weight.

[8] Needs increase from month to month; amounts given are for approximately 6 to 8 months. Requirements for protein and calcium are less if derived largely from human milk.

Fat. Allowances must be based at present more on food habits than on physiological requirements. It is desirable that fat be included in the diet to the extent of at least 20 to 25% of the total calories and that fat intake include essential unsaturated fatty acids (the linoleic and arachidic acids of natural fatty acids) to the extent of at least 1% of the total calories. For a very active person consuming 4500 calories and for children and for adolescent persons, it is desirable that 30 to 35% of the total calories be derived from fat. Since foodstuffs such as meat, milk, cheese, nuts, etc., contribute fat to the diet, it is necessary to use separated or "visible" fats such as butter, oleomargarine, lard, or shortenings to supply only one-third to one-half the amounts indicated.

Water. A suitable allowance for adults is 2.5 liters (2.5 quarts) daily. An ordinary standard is one milliliter for each calory of food. Most of this quantity is contained in prepared foods. At work or in hot weather, requirements may reach 5 to 13 liters daily. Water should be allowed *ad libitum*, since sensations of thirst usually serve as adequate guides to intake except for infants and sick persons.

Salt. The needs for salt and for water are closely interrelated. The average normal intake of sodium chloride is 10 to 15 grams daily, an amount which meets the requirements for a water intake up to 4 liters daily. When sweating is excessive, one additional gram of salt should be consumed for each liter of water in excess of 4 liters daily. With heavy work or in hot climates 20 to 30 grams daily may be consumed. Even then, most persons do not need more salt than usually occurs in prepared foods. After acclimatization persons produce sweat that contains only about 0.5 grams to the liter in contrast with a content of 2 to 3 grams for sweat of the unacclimatized person; after acclimatization the need for increase of salt beyond that of ordinary food disappears.

Iodine. The requirement for iodine is probably about 0.002 to 0.004 mg daily for each kg of body weight. This need is met by the regular use of iodized salt; its use is especially important in adolescence and pregnancy.

Phosphorus. The allowances should be at least equal to those for calcium in the diets of children and of women during the latter part of pregnancy and during lactation. In the case of other adults the allowances should be approximately 1.5 times those for calcium. In general it is safe to assume that if the calcium and protein needs are met through common foods, the phosphorus requirement also will be covered because the common foods richest in calcium and protein are also the best sources of phosphorus.

Copper. The requirement for adults is about 1 to 2 mg daily. Infants and children require approximately 0.05 mg for each kg of body weight. A good diet normally will supply sufficient copper.

Vitamin K. The requirement usually is satisfied by any good diet except for the infant in utero and for the first few days after birth. Supplemental vitamin K is recommended during the last month of pregnancy. When it has not been given in this manner, it is recommended for the mother preceding delivery or for the baby immediately after birth.

Folic acid (pteroylglutamic acid, vitamin B_c, L. casei factor or vitamin M). The quantitative requirement cannot be closely estimated from evidence now available.

THE VITAMINS

In compiling data for this revision certain facts became evident in making additions to the previous table. Some of the new factors which have now been added have not as yet been shown to be indispensable to man. The importance of some are only now being recognized and clinical experimentation is practically just beginning. However, it is known that the animal body does not function properly where the intake of these factors is low. Some of these factors have been shown to be synthesized in the intestines of some animals by the intestinal flora and consequently it is very difficult to produce a recognizable deficiency. Almost invariably a deficiency of any factor in man is accompanied by a deficiency of other factors and this gives the chief impetus to preparation of poly-vitamin products. Thus far no factor essential for lower animals, bacteria, etc., has been found which is not also essential for man. Some signs of deficiencies are apparently attributable to more than one vitamin. Some deficiencies are only partially cured by one or another vitamin while complete cure is obtained only by administration of all vitamins concerned. Most of the vitamins are interdependent upon the presence of each other for proper functioning.

INTERNATIONAL VITAMIN STANDARDS

1 Unit vitamin A ≐ 0.344 microgram (μg) pure vitamin A acetate ≐ 0.3 microgram pure vitamin A alcohol; 1 unit provitamin A = 0.6 microgram β-carotene.
1 Unit vitamin B_1 ≐ 3.3 micrograms thiamin chloride.
1 Unit vitamin C ≐ 50 micrograms of *l*-ascorbic acid.
1 Unit vitamin D ≐ 1 milligram of standard solution of irradiated ergosterol (corresponding to 0.1 microgram of the ergosterol used in its preparation or 0.025 microgram crystalline vitamin D_2 (viosterol or calciferol).

Name and Synonym	Physiological Effect	Sources*		
		Concentrates for Medicinal Use	Plant	Animal
Vitamin A Axerophthol Provitamins A (α-, β-, and γ-carotenes, cryptoxanthin, aphanin, aphanicin, echinenone, myxoxanthin, leprotene (and probably other carotinoids) Anti-infective Anti-ophthalmic (Fat soluble)	Increases resistance to infection of eyes, sinuses, ears, kidneys, skin, and mucous membranes. Prevents xerophthalmia, hyperkeratosis of skin and mucous membranes. Promotes appetite and growth. Essential for reproduction. The vitamin is stored in the body and is required at all ages. Deficiency results in night blindness and injury to the nervous system. Adult human requirements approximately 3000 to 5000 units daily.	Carotene, obtained from carrots or vegetables, is converted by the body into vitamin A. Unsaponifiable fractions of halibut liver oil, cod liver oil and other fish liver oils.	All yellow and green vegetables. Raw carrots, yellow turnips, yellow corn, spinach, squash, canned and fresh tomatoes, sweet potatoes, oranges, prunes, apricots and pimento peppers.	Halibut liver oil, cod liver oil and other fish liver oils, fresh milk, cream, butter, cheddar and cream cheese, egg yolk, liver and kidney.
Thiamin chloride Vitamin B_1 Anti-neuritic	Promotes appetite and digestion by stimulating metabolism. Vital to health at all ages. Required by the mother for reproduction and	Synthetic thiamine chloride. From yeast and wheat germ.	Whole grain cereals, green leafy vegetables, water cress, carrots,	Milk, cheese, raw oysters, brain, kidney and liver.

* See also table: Composition and Use of Foods.

THE VITAMINS (Continued)

Anti-beriberi (Soluble in water and in 90% alcohol; heat labile; acid stable; adsorbed from acid solution)	lactation. Prevents the diseases beriberi and polyneuritis. Promotes normal oxidation of carbohydrates in the body and formation of fat from carbohydrates. Adult human requirements approximately 1.5 to 2.0 milligrams daily.		canned tomatoes, green corn, baked potatoes, dried lima beans, turnips and nuts.	
p-Aminobenzoic acid PAB Chromotrichia factor Anti-gray-hair factor	Influences enzyme activity. In experimental rats it apparently prevents achromotrichia. Inhibits oxidation of adrenaline. Nutrilite for certain bacteria. Antagonizes sulfanilamide and sulfapyridine.	Synthetic. Extracts of yeast.	Yeast.	Widely distributed over entire plant and animal kingdoms.
Choline (Choline is replaceable by methionine or betaine with estimated efficacy of 30%; also replaceable by dimethylthetin or dimethyl-β-propiothetin)	Maintains integrity of tissues. In chickens it is necessary for normal nutrition and egg production. Deficiency results in marked deposition of liver fat. Acts as transmethylating agent. Deficiency in young rats produces severe renal lesions. Important in lipid metabolism. Deficiency causes a type of cirrhosis of the liver, hemorrhagic degeneration of kidneys, necrosis of kidney cortex, enlargement of spleen. Deficiency results in anemia in the rat. Necessary for normal growth and lactation of rat.	Synthetic choline chloride. As lecithin in phospholipids.	Rice bran, yeast.	Liver. Present in phospholipids of practically all animal and plant cells.
Ascorbic acid Vitamin C Cevitamic acid Anti-scorbutic (Soluble in water; heat labile at alkaline reaction)	Prevents and cures scurvy. Important in formation and maintenance of connective tissue in the body; essential for normal tooth and bone formation and strength of capillary walls. Inhibits dental caries, pyorrhea, certain gum infections, anorexia, anemia, failure of wound healing and susceptibility to infection. Important in carbohydrate metabolism and in controlling infective processes. Body stores readily depleted. Adult human requirements 75 to 100 milligrams daily.	Synthetic *l*-ascorbic acid.	Oranges, lemons, grapefruit, raw and leafy vegetables, raw apples, tomatoes, carrots and paprika.	Adrenal cortex, pituitary, ovary, thymus, intestinal wall, and milk.
Vitamin D Anti-rachitic (Fat soluble)	Prevents and cures rickets in young and osteoporosis in adults. Promotes absorption of calcium and phosphorus, and highly important for normal metabolism of these mineral elements in the young. Prevents spasmophilia and osteomalacia. Limited storage in the body. Approximate human requirements: for premature babies 600 to 800 units with milk; for full term infants 300 to 400 units with milk; for children 300 to 400 units	The effect of this vitamin is produced by the exposure of the body to direct sunlight or ultraviolet light. Ergosterol and foods exposed to (or irradiated with) ultraviolet. Unsaponifiable fractions of liver oils of halibut, cod, and many	Practically none.	Cod, halibut and other fish liver oils, butter, egg yolk, and fish.

Name and Synonym	Physiological Effect	Sources*		
		Concentrates for Medicinal Use	Plant	Animal
	and for pregnant and nursing women 800 units daily.	other fish. Cholesterol and several of its derivatives after exposure to ultraviolet light.		
Pantothenic acid Pantothen Filtrate factor Factor II Chick anti-dermatitis factor	Prevents dermatitis in chicks. Deficiency may produce lesions in nervous system or endocrine systems, or may involve skin or hair. May play a part in maintaining integrity of nervous tissue. Necessary in treatment of peripheral neuritis along with other B-vitamins. Prevents hemorrhagic adrenals and achromotrichia in rats. Prevents duodenal ulcers and atrophy of duodenal mucosa. Essential for growth in various experimental animals and plants. Needed for reproduction in chicks and increases egg hatchability. Is necessary for acetylations in the rat. It is a constituent of coenzyme A. As coenzyme A it yields citrate from acetate and oxaloacetate.	Synthetic calcium *d*-pantothenate. Liver and yeast extracts.	Rice bran, wheat bran, brewer's yeast, Irish potato, taro root, alfalfa, wheat germ, molasses, peanuts, cabbage, cucumbers, and rolled oats.	Mammalian liver, egg yolk, eggs, canned salmon, whole milk, kidney, heart, spleen, brain, pancreas, tongue, lung, muscle, beef.
Pyridoxin Pyridoxal Pyridoxamine Vitamin B_6 Adermin Factor Y Anti-dermatitis Anti-acrodynia factor (Soluble in water and in dilute alcohol; heat and acid stable)	Deficiency of this vitamin causes dermatitis in rats; anemia in dogs and pigs, and is presumably essential for hemoglobin formation. Controls both iron and copper absorption in rats. In experimental animals deficiency produces convulsions resembling human epileptic fits. Requirements proportional to metabolism. Apparently concerned with metabolism of the amino acids to carbohydrates. Deficiency impairs liver function, produces erythrodemic dermatosis, impairs growth.	Synthetic pyridoxin. From the germ and bran of wheat and rice; yeast, and liver extracts.	Grains, chiefly in the germ, yeast, maize, and molasses, seeds, legumes, spinach, and lettuce.	Liver, heart muscles, milk, and egg yolk.
Riboflavin Vitamin B_2 Vitamin G (Soluble in water and in dilute alcohol; heat and acid stable)	Plays an important role in vision mechanism. In fowls important in production and hatchability of eggs. Deficiency produces cheilosis, glossitis, seborrheic lesions about eyes and nose, vascularizing keratitis, and mild photophobia. Is a component of several enzymes. Plays part in metabolism of amino acids and carbohydrates. Deficiency produces loss of	Synthetic *d*-riboflavin. From milk whey, liver and yeast. Fermentation residues.	Fruits, leafy vegetables, soy beans, wheat germ, yeast.	Kidney, liver, milk, eggs.

* See also table: Composition and Use of Foods.

THE VITAMINS (Continued)

	hair, injury to nervous system, failure to grow, yellow liver, anemia and death. Adult human requirements approximately 2 to 3 milligrams daily.			
Vitamin E α-, β-, and γ-Tocopherols Anti-sterility (Fat soluble)	Absence of this vitamin causes sterility in either sex. It is stored in the body to a certain degree. Exerts favorable influence on growth. Limited value in certain cases of muscular dystrophy and amyotropic lateral sclerosis. Aids in resisting protein deficiency and prevents nutritional liver damage.	Synthetic *dl*-α-tocopherol. Unsaponifiable fraction of wheat germ oil.	Vegetable oils, lettuce, beans, whole wheat, rice, barley, corn, and water cress.	Meat, liver, milk, and eggs.
Nicotinic acid Niacin Nicotinic acid amide Niacin amide Anti-pellagra Pellagra preventive (P-P) factor	Prevents and cures black tongue in dogs and pellagra in man. Is a component of several enzymes. Influences carbohydrate, protein, water, and heavy metals metabolism. Deficiency produces a certain type of anemia. Adult human requirement approximately 10 to 20 milligrams daily.	Synthetic nicotinic acid, its amide, and all hydrolyzable nicotinoyl derivatives. From liver and yeast.	Yeast, wheat germ, peas, beans, green leafy vegetables.	Liver, lean meat, milk, egg yolk.
Vitamin K Anti-hemorrhagic Coagulation factor Prothrombin factor Phylloquinones Menadione (2-methyl-1, 4-naphthoquinone) (Fat soluble, heat stable, alkali labile)	Promotes normal blood coagulation time. In chicks it prevents intestinal, subcutaneous and intramuscular hemorrhage. Deficiency reduces prothrombin formation, hemorrhagic diathesis in newborn, certain types of hepatic and biliary diseases.	Synthetic K-vitamers; i.e., many related 1,4-naphthoquinones and compounds readily converted to them, most important is 2-methyl-1, 4-naphthoquinone, which replaces commercially the vitamin, and is known commercially as menadione.	All green vegetables and green leaves, tomatoes, oat sprouts, dried carrot tops, hemp-seed oil, cotton-seed oil, soy-bean oil, and bacterial action on rice bran.	Hog-liver fat, egg yolk, bacterial action on casein and fish meal. K_2 from putrefied fish meal.
Biotin Vitamin H Coenzyme R Anti-egg-white factor Curative factor of egg-white injury Bios II Bios II_b Factor X Factor W	Essential in vital economy of animals and in normal pigment metabolism. Takes part in carbon dioxide fixation; deaminase activity stimulates lipid utilization. Important in intermediary metabolism. Prevents dermatitis. Pervents perosis in chicks and fatty livers. Deficiency results in seborrheic desquamative dermatitis, emaciation and death. Nutrilite for certain bacteria and for yeast. It is antagonized by avidin which occurs in egg white.	Synthetic. Extracts of egg yolk, liver, milk-sugar residues, fermentation residues.	Widely distributed in nature. Yeast, seeds, nuts, tomatoes, carrots, corn and other vegetables.	Liver, kidney, pancreas, egg yolk, pork, and milk. Occurs in small amounts in all mammals and birds; tissue of eye only exception found so far.
Inositol (Meso-inositol) Bios I Anti-alopecia factor	Promotes growth, cures baldness in mice, important in fat metabolism, prevents fatty liver, favors growth of yeast and other microorganisms.	Liver extracts. Wheat bran extracts in the form of the hexa-phosphate ester (phytic acid) which on hydrolysis yields inositol.	Citrus fruits, nuts, yeast, various whole cereals and grains.	Muscle, kidney, liver, brain, milk, and eggs.

THE VITAMINS

Name and Synonym	Physiological Effect	Sources*		
		Concentrates for Medicinal Use	Plant	Animal
Folic acid Pteroylglutamic acid (L. casei factor)	Nutrilite for yeast and certain bacteria. Anti-anemia factor. Appears to be a growth factor for rats. Deficiency in mice is accompanied by reduction in cellular elements of blood and arrest of bone marrow maturation.	Extracts of yeast, milk sugar residue, spinach. Synthetic pteroylglutamic acid.	Yeast, mushrooms. Leaves of many plants.	Milk. Present in all animal tissues.
Citrin Vitamin P Permeability vitamin	Promotes tissue and capillary permeability. Prolongs life of scorbutic guinea pigs. Deficiency causes nutritional purpura.	Extracts of citrus fruits.	Citrus fruit juices and the leaves of several plants.	None.
Vitamin B_{12} Antipernicious factor Animal protein factor	Prevents: pernicious anemia; megaloblastic anemia of infancy; nutritional macrocytic anemia; sprue; nutritional glossitis. Required for gestation and lactation.	Liver extracts.		Liver, milk, fish meal.

* See also table: Composition and Use of Foods.

COMPOSITION OF COWS MILK

(According to Van Slyke)

Whole milk = 100

- Water = 87.1
- Solids = 12.9 (100.0)
  - Fat 3.9
  - Non-fat 9.0 (12.9)
    - Nitrogen compds. 3.2
    - Milk sugar 5.1
    - Ash 0.7 (9.0)
      - Casein 2.5
      - Albumin 0.7 (3.2)
- Gases — CO_2, N_2, O_2

(According to Babcock)

Whole milk = 100

- Casein 3.00
  Albumin 0.60
  Galactin 0.20
  Fibrin
  Globulin
  (3.80) — Containing nitrogen = 3.8
- Lactose 4.5
  Citric acid 0.1
  (4.6) = 4.6
- Solids not fat = 9.1
- Potassium oxide 0.175
  Sodium oxide 0.070
  Calcium oxide 0.140
  Magnesium oxide 0.017
  Ferric oxide 0.001
  Sulfur trioxide 0.027
  Phosphorus trioxide 0.170
  Chloride 0.100
  (0.700) — Ash = 0.7
- Olein, Palmitin, Stearin, Myristin, Butin (trace), Caprylin (trace), Caproin, Caprinin (trace), Butyrin — Glycerides of insoluble and non-volatile acids = 3.3
- Glycerides of soluble and volatile acids = 0.3
- Fat = 3.6
- Total solids = 12.7
- Water = 87.3

Table showing the per cent total solids in milk corresponding to the per cent of fat and Quevenne lactometer reading.*

To use the table, first find in the column at the extreme left the number correspond-

Per Cent Fat	Quevenne Lactometer Reading at 15.56°C (60°F)

*See also a table: *Conversion Table for Quevenne and New York Board of Health Lactometer Readings to Specific Gravity*

TOTAL MILK SOLIDS

The percentage of total milk solids may be calculated from the following expression: (A+B+0.14) = % total solids; where A = % butter fat×1.2; and B = Quevenne lactometer reading × 0.25.

SOLIDS

ing to the % of butterfat, then in the same line with this and in the same column as the observed lactometer reading as given across the top of the table will be found the % of total solids.

STANDARDIZATION OF MILK AND CREAM

Pearson's Square Method.

The following procedure is a convenient method for calculating the relative parts by weight of two materials containing the same component but in different amounts which are to be mixed in order to obtain a product in which the component is present in an amount lying between that of the two starting products. Thus, to calculate the relative parts by weight of a 3% butter fat milk and a 40% butter fat cream which would be required in order to obtain 500 pounds of a 5% butter fat milk, proceed as follows: Draw a square and place the number corresponding to the desired % in the center (Fig. 1) and on the two corners at the left place the numbers corresponding to the % of starting materials (Fig. 2); subtract the number in the center of the square from the larger of the two numbers on the left and write this number on the corner diagonally opposite the larger of the numbers on the left (Fig. 3); then subtract the smaller of the two numbers on the left from the number in the center and write the result on the remaining corner (Fig. 4). The two numbers on the right side of the square represent the parts by weight of each of the starting products and which in this example gives the answer that 35/37 of 500 (or 473 pounds) of 3% butter fat milk and 2/37 of 500 (or 27 pounds) of 40% butter fat cream when mixed will give 500 parts of 5% butter fat milk.

NATURAL WATERS FOR INDUSTRIAL USE

Cf. W. D. Collins, *Chem. and Eng. News* **21**, *1062 (1943)*.
Reproduced by Permission.

SURFACE AND GROUND WATERS

Typical natural waters available for industrial use in the United States are shown in *Table I*. They have been classified into five types as follows:

Type A. Catskill supply of New York City. This type is a *natural soft water*. For practical purposes it may be considered the equivalent of distilled or rain water and may contain not more than approximately 30 parts per million of dissolved mineral matter. Public water supplies of this type are the Catskill supply of New York City, the supply of Boston and surrounding territory, the Hetch Hetchy supply of San Francisco, and the supply of Asheville, N. C. Rivers and lakes in Maine and other New England states, and streams and lakes in or near mountains may supply these clear waters of low mineral content. The hardness of these natural waters is less than the best that could be obtained by softening methods in use before development of the ion-exchange systems. The very soft waters have a tendency to be corrosive and may require treatment or special precautions to prevent damage from corrosion.

Type B. Niagara River, filtered for public supply of Niagara Falls, N. Y. This type is a *hard water* intermediate between *Type A* and *Type C*. This water, represented by the waters of the Great Lakes, except Lake Superior, is more like the soft waters than the real hard waters. As such it has been used for many domestic supplies but for industrial uses where hardness is detrimental the water must be softened. Public supplies of this type of water are those in Detroit, Milwaukee, Chicago, Cleveland, Sandusky, Toledo, Erie, Buffalo, Niagara Falls, and many smaller places along the lakes and the St. Lawrence River.

Type C. Wells 30 to 60 feet deep used for public supply of Dayton, Ohio. This type is a genuinely *hard water* as commonly used throughout the industrial areas in the heart of the country. These hard waters are the most widely distributed throughout the United States and the water obtained from the wells is so hard that softening is needed to make it acceptable for general domestic use or for most industrial uses.

Type D. Well 2,000 feet deep used for public supply of Maywood, Ill. This type contains enough chloride to require a separate listing. In a few waters nitrate is present as a major constituent but these waters may be classed as variants of the *hard water* type if their total mineral content is in the range of usable waters.

Type E. Well 330 feet deep at Smithfield, Va. This type is representative of a smaller but distinct class of *naturally softened waters*. Their hardness may be well below the average hardness of the waters classed as soft whereas their total mineral content may be well up in the range of the really hard waters. Many of the softened waters in Louisiana and Mississippi are highly colored. The softened, or sodium bicarbonate waters, are found in widely scattered areas but they are somewhat more common in the Atlantic and Gulf Coastal Plain.

NATURAL WATERS FOR INDUSTRIAL USE

Salt Waters. This class may include all waters not considered generally usable. **Sea water** may be taken as the typical salt water. It has about 35,000 parts per million of dissolved salts. Cf. Clarke, "The Data of Geochemistry," *U. S. Geol. Survey Bull.* 770 (*1924*). It is characteristic of sea water that the magnesium greatly exceeds the calcium. Most **brines from inland wells** carry more calcium than magnesium. They also have a smaller proportion of sulfate than sea water and may have much more dissolved mineral matter, often running up to 200,000 or 300,000 parts per million. Such brines may be the raw materials of certain chemical industries.

General Characteristics. An important characteristic of natural waters is the hydrogen-ion concentration. In general the *pH* of natural waters tends to center around 7.0 or a little above. Well waters low in dissolved solid mineral constituents and high in carbon dioxide are often found with a *pH* below 6.0, and not too rarely with a *pH* below 5.0. Sodium bicarbonate waters may have a *pH* of 8.0 or more. **Temperature** is an important factor in relation to industrial use. Cf. Collins, "Temperature of Water Available for Industrial Use in the United States," *U. S. Geol. Survey Water-Supply Paper* 520-F (1925). Ground waters normally have a constant temperature that is close to the mean annual air temperature for water from depths of 30 to 60 feet. Below 60 feet the temperature increases about 1° F. for each increase in depth of from 60 to 100 feet according to location. Surface water temperatures are variable and not wholly predictable. Reservoirs and lakes may show stratification. In deep lakes a top layer of 20 to 30 feet responds to atmospheric changes while the temperature at greater depths remains constant.

In *Table I* following, the waters used industrially are illustrated by analyses from a report on industrial water supplies that gives analyses for 670 supplies used by about 57,000,000 consumers. The extent to which the five analyses can be taken as representative of waters available for industrial use is as follows:

Type	Number of Supplies	Number of States	Population Supplied
A	131	25	11,170,968
B	75	29	11,581,024
C	47	16	2,153,459
D	19	10	600,785
E	8	3	128,583

Although *Table I* is based on the public supplies of only 670 places, including the larger places in each state, the general conclusions can safely be applied to water supplies that are available for industrial use in the United States. Cf. Collins, Lamar, and Lohr, "The Industrial Utility of Public Water Supplies in the United States, 1932," *U. S. Geol. Survey Water-Supply Paper* 658 (*1934*).

RIVER WATERS

Analyses of river waters are shown in *Table II*. River waters carry widely varying amounts of suspended matter. Some streams regularly have only a few parts per million of suspended matter. At times of heavy rains or rapid melting of snow they

may carry much more. Rivers like the Missouri and Colorado normally carry from a few hundred to several thousand parts per million of suspended matter. The average load in the Missouri is of the order of magnitude of about 2,000 parts per million. The average load of suspended matter in the Colorado River at Grand Canyon, Ariz., is about 1 per cent, 10,000 parts per million. At times the Colorado at Grand Canyon has carried as much as 12 per cent, 120,000 parts per million, for a day. The temperature of river waters follows the changes in air temperature, with a lag that is dependent on many conditions. In a very general way it has been found that the mean monthly temperature of a river water at any point is likely to be within a few degrees of the mean monthly air temperature unless there are conditions that affect the temperature strongly. There is a lag in the rise of spring and early summer temperature in streams that are fed by melting snow.

*Dosage successful in New York City's supply.
†These organisms cause trouble other than odor.
‡These organisms have been affected by chlorine producing characteristic odor and in many cases controlled by dosage ranging from 0.3 to 3.0 ppm, depending largely upon the amount of organisms.
§Controlled by excess caustic lime, 5 ppm in the case of diatoms (48 hrs.).

DRINKING WATER STANDARDS

Condensed from Standards adopted by the United States Treasury Department, February 6, 1946.

As to Bacteriological Quality.

Applications *A1* and *A2* shall govern when ten-milliliter (10 ml) portions are used and applications *B1* and *B2* shall govern when one hundred-milliliter (100 ml) portions are used.

(*A1*) Of all the standard ten-milliliter (10 ml) portions examined per month in accordance with specified procedure, not more than ten (10) per cent shall show the presence of organisms of the coliform group.

(*A2*) Occasionally three (3) or more of the five (5) equal ten-milliliter (10 ml) portions constituting a single standard sample may show the presence of organisms of the coliform group, provided that this shall not be allowable if it occurs in consecutive samples or in more than:

(*a*) Five (5) per cent of the standard samples when twenty (20) or more samples have been examined per month.

(*b*) One (1) standard sample when less than twenty (20) samples have been examined per month.

(*B1*) Off all the standard one hundred-milliliter (100 ml) portions examined per month in accordance with the specified procedure, not more than sixty (60) per cent shall show the presence of organisms of the coliform group.

(*B2*) Occasionally all of the five (5) equal one hundred-milliliter portions constituting a single standard sample may show the presence of organisms of the coliform group, provided that this shall not be allowable if it occurs in consecutive samples or in more than:

(*a*) Twenty (20) per cent of the standard samples when five (5) or more samples have been examined per month.

(*b*) One (1) standard sample when less than five (5) samples have been examined per month.

As to Chemical and Physical Characteristics.

The turbidity of the water shall not exceed 10 ppm (silica scale), nor shall the color exceed 20 (standard cobalt scale). The water shall have no objectionable taste or odor, and shall not contain an excessive amount of soluble mineral substance, nor excessive amounts of any chemicals employed in treatment.

For waters softened by the lime soda process the total alkalinity produced should not exceed the hardness by more than 35 ppm (calculated as $CaCO_3$).

For chemically treated waters the phenolphthalein alkalinity (calculated as $CaCO_3$) should not be greater than 15 ppm plus 0.4 times the total alkalinity. This requirement limits the permissible *pH* to about 10.6 at 25°C. The normal carbonate alkalinity should not exceed 120 ppm.

DRINKING WATER STANDARDS

Lead (Pb) shall not exceed 0.1 ppm. Selenium shall not exceed 0.05 ppm.
Arsenic shall not exceed 0.05 ppm. Chromium VI shall not exceed 0.05 ppm.
Fluorides shall not exceed 1.5 ppm.

Salts of barium, hexavalent chromium, heavy metal glucosides or other substances with deleterious physiological effects shall not be added to the system for water treatment purposes.

The following chemical substances which may be present in natural or treated waters should preferably not occur in excess of the following concentrations where other suitable supplies are available:

Copper (Cu) should not exceed 3.0 ppm. Zinc (Zn) should not exceed 15 ppm.
Iron (Fe) and manganese (Mn) together should not exceed 0.3 ppm.
Magnesium (Mg) should not exceed 125 ppm.
Chloride (Cl) should not exceed 250 ppm.
Sulfate (SO_4) should not exceed 250 ppm.
Phenolic compounds should not exceed 0.001 ppm in terms of phenol.

Total solids should not exceed 500 ppm for a water of good chemical quality. However, if such water is not available, a total solids content of 1,000 ppm may be permitted.

STABLER'S REACTION COEFFICIENTS

The valence of a radical divided by its atomic or molecular weight.

Positive ions	Reaction Coefficient	Negative ions	Reaction Coefficient
Aluminum, Al	0.1112	Bicarbonate, HCO_3	0.0164
Calcium, Ca	0.0499	Carbonate, CO_3	0.0333
Hydrogen, H	0.9922	Chloride, Cl	0.0282
Iron, Fe"	0.0358	Hydroxide, OH	0.0588
Magnesium, Mg	0.0822	Nitrate, NO_3	0.0161
Potassium, K	0.0256	Sulfate, SO_4	0.0208
Sodium, Na	0.0435		
Alkalinity, $CaCO_3$	0.0200		
Free CO_2, CO_2	0.0454		

The reacting value of a radical, which is identical with the terms "milliequivalent" or "milligram equivalent" of other writers, is obtained by use of the above table; the parts per million of a radical multiplied by its reaction coefficient gives the reacting value of that radical; for example, if a water analysis showed the sample to contain 25 parts per million of magnesium then the reacting value of Mg, written rMg, would be 25×0.0822 or 2.055.

FORMULAS FOR WATER SOFTENING REQUIREMENTS

The terms in the formulas are in parts per million except those expressed as reacting values (r). Abbreviations: Alk—alkalinity as $CaCO_3$; TH—total hardness as $CaCO_3$.

Pounds of lime (90% CaO) required per 1000 gal.

$0.26\ (r\mathrm{Fe}+r\mathrm{Al}+r\mathrm{Mg}+r\mathrm{H}+r\mathrm{HCO_3}+r\mathrm{CO_2})$

or $0.00931\mathrm{Fe}+0.0288\mathrm{Al}+0.0214\mathrm{Mg}+0.258\mathrm{H}+0.00426\mathrm{HCO_3}+0.0118\mathrm{CO_2}$

Other simpler formulas for this computation are:

$0.26\ (r\mathrm{CO_2}+r\mathrm{Mg}+r\mathrm{Alk})$

or $0.26\ [r\mathrm{Na}+r\mathrm{Ca}+2r\mathrm{Mg}+r\mathrm{CO_2}-(r\mathrm{SO_4}+r\mathrm{Cl})]$

or $0.0052\ (4.115\mathrm{Mg}+\mathrm{Alk}+2.27\ \mathrm{CO_2})$

or $(0.44\ \mathrm{Alk}+\mathrm{CO_2})\times 0.0118+[4.115\ \mathrm{Mg}\times 0.0052]$

Pounds of soda ash (58% test or 100% pure) required per 1000 gal.

$0.44\ (r\mathrm{Fe}+r\mathrm{Al}+r\mathrm{Ca}+r\mathrm{Mg}+r\mathrm{H}-r\mathrm{CO_3}-r\mathrm{HCO_3})$

or $0.0157\mathrm{Fe}+0.0489\mathrm{Al}+0.022\mathrm{Ca}+0.0362\mathrm{Mg}+0.437\mathrm{H}-0.0147\mathrm{CO_3}-0.0722\mathrm{HCO_3}$

Other simpler formulas for this computation are:

$0.44\ (r\mathrm{Ca}+r\mathrm{Mg}-r\mathrm{Alk})$

or $0.44\ [(r\mathrm{Ca}+r\mathrm{Mg})-r\mathrm{CO_3}]$

or $0.0088\ (4.115\ \mathrm{Mg}+2.495\ \mathrm{Ca}-\mathrm{Alk})$

or $0.0088\ (\mathrm{TH}-\mathrm{Alk})$

WATER ANALYSIS

Hypothetical Results Calculated from Alkalinity and Non-carbonate Hardness Determinations.

Compiled by O. F. Schoepfle

M is methyl orange alkalinity
P is phenolphthalein alkalinity
N or NCH is non carbonate hardness

T or TH is total hardness
C is causticity
N⁻ is negative NCH

A. S. T. M. CLASSIFICATION OF COALS BY RANK

American Society for Testing Materials, Standards, Pt. III, p. 1 (1939); by permission.

Class	Group	Limits of FC or btu mineral-matter-free basis	Requisite physical properties
I. Anthracite	1. Meta-anthracite	Dry FC, 98%	
	2. Anthracite	Dry FC, 92%–98%	
	3. Semianthracite	Dry FC, 86%–92%	Non-agglomerating[a]
II. Bituminous[c]	1. Low volatile bituminous coal	Dry FC, 78%–86%	
	2. Medium volatile bituminous coal	Dry FC, 69%–78%	
	3. High volatile A bituminous coal	Dry FC, <69%; and moist[b] btu, 14,000+[d]	
	4. High volatile B bituminous coal	Moist[b] btu, 13,000–14,000	
	5. High volatile C bituminous coal	Moist btu, 11,000–13,000	Either agglomerating or non-weathering*
III. Subbituminous	1. Subbituminous A coal	Moist btu, 11,000–13,000	Both weathering and non-agglomerating
	2. Subbituminous B coal	Moist btu, 9,500–11,000	
	3. Subbituminous C coal	Moist btu, 8,300–9,500	
IV. Lignitic	1. Lignite	Moist btu, <8,300	Consolidated
	2. Brown coal	Moist btu, <8,300	Unconsolidated

FC = fixed carbon; btu = British thermal units

[a] If agglomerating, classify in low-volatile group of the bituminous class.

[b] Moist btu refers to coal containing its natural bed moisture but not including visible water on the surface of the coal.

[c] There may be non-caking varieties in each group of the bituminous class.

[d] Coals having 69% or more fixed carbon on the dry, mineral-matter-free basis shall be classified according to fixed carbon, regardless of btu.

* There are three varieties of coal in the high-volatile C bituminous coal group; viz., variety 1, agglomerating and non-weathering; variety 2, agglomerating and weathering; variety 3, non-agglomerating and non-weathering.

FORMULAS FOR CALCULATING MINERAL-FREE btu AND FIXED CARBON

FC = % Fixed carbon A = % Ash
M = % H_2O S = % Sulfur

In cases of litigation, coal samples containing more than 1% CO_2 as carbonate must be floated on a heavy liquid to reduce the amount to less than 1%.

The long method (or Parr) formula used only for referee purposes:

$$\%\ \text{Dry, mineral-free } FC = \frac{FC - 0.15S}{100 - (M + 1.08A + 0.55S)} \times 100$$

$$\text{Moist, mineral-free } btu = \frac{btu - 50S}{100 - (1.08A + 0.55S)} \times 100$$

The short (or A. S. T. M.) approximation formula:

$$\%\ \text{Dry, mineral-free } FC = \frac{FC}{100 - (M + 1.1A + 0.1S)} \times 100$$

$$\text{Moist, mineral-free } btu = \frac{btu}{100 - (1.1A + 0.1S)} \times 100$$

HEAT OF COMBUSTION OF COAL FROM ANALYSES

The usual formula employed in calculating the heat of combustion of coal from an ultimate analysis is that of Dulong:

$$\text{BTU/pound} = 14{,}544C + 62{,}028\left(H - \frac{O}{8}\right) + 4050S$$

where C, H, O, and S are the decimal percents of carbon, hydrogen, oxygen, sulfur found on ultimate analysis made on the "as received" basis.

A proximate analysis of coal gives moisture, volatile matter, fixed carbon and ash. It is possible to compute the heat of combustion of coal from the values obtained in a proximate analysis by first finding the percent of carbon, hydrogen and oxygen by means of the formulas below and then substituting in Dulong's formula given above.

The method is as follows:—From the values of a proximate analysis find the percent of volatile matter (V) and fixed carbon *on an ash- and moisture-free basis.* These two values should add up total 100%. Then,

$$\%H = \%V\left(\frac{7.35}{\%V + 10} - 0.013\right)$$

$\%N = 0.07V$ for anthracite and semi-anthracite coals.
$\%N = 2.10 - 0.012V$ for bituminous and lignite coals.
$\%C$ = Fixed $C + 0.02V^2$ for anthracite coals.
$\%C$ = Fixed $C + 0.9\ (V - 10)$ for semi-anthracite coals.
$\%C$ = Fixed $C + 0.9\ (V - 14)$ for bituminous coals.
$\%C$ = Fixed $C + 0.9\,(V - 18)$ for lignite.

Sulfur increases V, therefore the volatile carbon is too high by the extent of the sulfur in the coal.

Example.—A bituminous coal from Jefferson, Pa. gives a proximate anaylsis as follows: moisture, 2.59%; volatile matter, 30.41%; fixed carbon, 59.08%; ash, 7.9%.
The %ash plus %moisture = 7.9 + 2.59 = 10.49
Therefore,

$$\frac{30.41}{100 - 10.49} \times 100 = 33.97\%$$ volatile matter on ash- and moisture-free basis.

$$\frac{59.08}{100 - 10.49} \times 100 = 66.00\%$$ fixed carbon on ash- and moisture-free basis.

$$H = 33.97\left(\frac{7.35}{33.97 + 10} - 0.013\right) = 5.23\%H$$

$N = 2.10 - 0.012 \times 33.97 = 1.69\%N$
$C = 66.00 + 0.9\,(33.97 - 14) = 83.97\%C$
$83.97 \times 0.8951 = 75.16\%C$ as received
$5.23 \times 0.8951 = 4.68\%H$ as received
$1.69 \times 0.8951 = 1.51\%N$ as received
7.9% ash
2.59% moisture
91.84%, therefore $100 - 91.94 = 8.16\%$ oxygen

Then by substitution of the values above in the Dulong formula

$$14{,}544 \times 0.7516 + 62{,}028\left(0.0468 - \frac{0.0816}{8}\right) = 13{,}201 \text{ BTU/pound.}$$

The experimental value reported for this coal was 13,860 BTU/pound.

COMBUSTION CON-

The high (gross) heat value is the value obtained by burning the gas in a Junker's calorimeter, which assumes that the products of combustion are cooled to the initial temperature and includes the heat of condensation of the water formed by the combustion; the low (net) heat value differs from the high (gross) value by the heat of vaporization of water and is calculated from the gross by subtracting the heat of

Name and formula	Mol. wt.	Sp. Gr.	B.T.U. per cu. ft., dry, 30 in. pressure

COMBUSTION CONSTANTS AND COMPOSITION OF

The coal gas, coke-oven gases, oil gas and carburetted water gas contain in addition small amounts of benzene and oxygen. The heat values are calculated from the values as given in the table under COMBUSTION CONSTANTS OF GASES.

	Blast-furnace gas	Blue water gas	Carburetted water gas	Coal gas	Coke-oven gas

STANTS OF GASES

vaporization of water at 60°F; thus, in the low (net) value the assumption is made that all of the products of combustion with the exception of the water have been cooled to the initial temperature; the flue products are calculated upon air with a composition of 79% nitrogen and 21% oxygen. The flame temperatures are not corrected for dissociation.

REPRESENTATIVE MANUFACTURED AND NATURAL GASES

The flame temperatures are not corrected for dissociation. The air required, products of combustion, B. T. U. of gas-air mixture and the flame temperature are based upon air with 21% oxygen and 79% nitrogen.

FLAME TEMPERATURES

Reprinted by permission from "Combustion Flames and Explosions of Gases," by Lewis and von Elbe, published 1938 by Macmillan.

Except as noted otherwise, the flame temperatures listed in the following table were determined by the sodium line-reversal method with a totally colored flame for moist mixtures at room temperature. The values given are the maximum flame temperatures determined for the given combustible or combination of combustibles with inert gas. In a few cases a number of values are given for different mixture compositions. All compositions are given on the dry basis.

The experimental flame temperatures are probably all influenced somewhat by heat losses, excitation lag and intermixing with the surrounding atmosphere. However, these disturbances do not cause excessive discrepancies from the theoretical flame temperatures, and the values may be taken as an approximate indication of the flame temperatures of the mixtures given.

A large number of calculated flame temperatures are to be found in the literature. They are not included in the table because they are generally based on inexact thermochemical data. Similarly, many experimental values have been omitted, since they were determined under specialized and sometimes ill-defined conditions.

NICHROME RESISTANCE WIRE

SUGGESTIONS ON DESIGN OF NICHROME HEATING ELEMENTS

Reprinted from Catalog R-28, Driver-Harris Company by Permission.

The table below gives the size of "Nichrome" suggested for a given number of watts at 110 volts. The sizes are selected to operate at approximately 1500°F. in open coils and are suitable for electric irons, toasters, hot plates, space heaters, etc.

NICHROME WIRE. 110 VOLTS

Watts	Amperes	B. & S. Size	Ohms 75° F	Length	
				21 Ft.	2 Ins.
250	2.27	25	43.6		
300	2.72	24	36.4	22	0
350	3.2	23	31.0	24	0
400	3.64	23	27.2	21	0
450	4.10	22	24.1	23	5
475	4.32	22	23.0	22	4
500	4.55	22	21.8	21	0
550	5.0	21	19.8	24	5
575	5.23	21	18.9	23	2
600	5.46	21	18.1	22	4
615	5.6	20	17.7	27	6
640	5.82	20	17 0	26	6
660	6.0	20	16.5	25	8
700	6.36	20	15.6	24	4
750	6.81	19	14.5	28	5

For voltages other than 110 divide the number of watts required at the given voltage by the voltage factor below. Select the nearest number of watts in the 110 volt table, multiply the length in 110 volt table by the voltage factor. Suppose an electric iron takes 550 watts and the supply voltage is 100. Factor for 100 volts is .91 and $\frac{550}{.91}$ = 605 watts.

Nearest value in 110 volt table is 600 watts which requires 22′ 4″ of size 21 wire. This gives the size to be used on 110 volts, but the length should be 0.91×22′4″ or 20′4″. The winding for 550 watts, 100 volts would then be 20′4″ of size 21 "Nichrome" wire.

VOLTAGE FACTORS ON BASIS OF 110 VOLTS

Voltage	100	120	150	200	220	240	32
Factor	.91	1.09	1.36	1.82	2.0	2.18	0.29

ADVANCE RESISTANCE WIRE

Reprinted from Catalog R-28, Driver-Harris Company by Permission.

Specific resistance 294 ohms per circular mil-foot at 20°C. (68°F.). The change of resistance with change of temperature is negligible. Thermal E. M. F. against copper is approximately 0.043 milli-volts per degree Centigrade, between 0°C. and 100°C.

MANGANIN RESISTANCE WIRE

Reprinted from Catalog R-28, Driver-Harris Co. by Permission.

Specific resistance 290 ohms per circular mil-foot at 20°C. (68°F.). Temperature coefficient over the range of 15° to 35°C. (59° to 95°F.), with the peak of the curve at 25°C. (77°F.), will be between .00002 and .000005 per degree C. Thermal E. M. F. against copper not over 0.003 millivolts per degree centigrade, between 0°C. and 100°C.

TEMPERATURE CORRECTIONS

(Based on A. I. E. E. Standards)

Temperature Coefficient of Resistance. At a temperature of 25°C the "constant mass" temperature coefficient of resistance of standard annealed copper, measured between potential points rigidly fixed to the wire is 0.00385 or 1/259.5 per Centigrade degree. Resistance values of copper wire given in tables at 25°C may be corrected for any temperature by means of the following formula— $Rt = R_{25}[1+0.00385(t-25)]$, where Rt is the resistance in ohms at a temperature t°C; R_{25} is the resistance in ohms at 25°C; and, t is the temperature of wire in degrees Centigrade.

PROPERTIES OF MATERIALS OF CONSTRUCTION

Chemical and Metallurgical Engineering, 39, 651-8 (1932); Perry, *The Chemical Engineers' Handbook*, McGraw-Hill Co., publishers; by permission.

GLASS LINED AND ENAMELED STEEL

(A) Coefficients of Heat Transfer for Typical Chemical Enamels.

These coefficients are of course, only relative, and are dependent to a large extent on the amount of agitation of the contained materials. Good agitation may increase values by as much as 20 to 25 per cent. Abbreviations: K is in B. T. U.s per sq. ft. per hour per °F. of temperature difference. K_1 refers to the heat transfer from steam to water being heated, while K_2 refers to the heat transfer from steam to boiling water.

1. Dry dust enamel for very severe chemical service.
   (a) Pfaudler No. 17, $K_1 = 60$; $K_2 = 80$
   (b) Pfaudler No. 11, $K_1 = 50$; $K_2 = 70$
2. Spray enamel for organic acids and less corrosive mineral acids.
   (a) Pfaudler No. 71, $K_1 = 125$; $K_2 = 150$
3. Spray dust enamel for mineral acids in general storage service, usually for equipment of large capacities.
   (a) Pfaudler No. 186, $K_1 = 90$; $K_2 = 100$

(B) Other Physical and Mechanical Properties.

Such physical properties of enamel as the coefficient of expansion, tensile strength, etc., are generally meaningless unless considered in connection with the steel on which the lining is applied. Ability to withstand rapid thermal change is tested in an automatic machine by intermittently heating enamel plates to 450°F. and then dipping them into ice water. However, both temperature and corrosion conditions to be met in each service application should be definitely ascertained and this information supplied to the manufacturer.

CHEMICAL STONEWARE

Ultimate compressive strength	82,000 – 115,000 lbs./in.²
Ultimate tensile strength	1,650 – 4,300 lbs./in.²
Modulus of elasticity	$1.05 - 5.95 \times 10^6$ lbs./in.²

Effect of aging	Nil	Slight	Tendency to harden at normal temp.
Machining qualities	Good	Can be ground	.....
Available forms	Pipe and fittings, tank and pipe linings, misc. forms	Tank linings, hose, misc. forms	Tank, vat, pipe, valve linings for chemical and abrasive protection

VULCANIZED FIBER

Marketed forms	Sheets, tubes and rods
Thickness	0.004 and up
Forming properties	Good
Machining qualities	Good
Colors	Red, brown, white, gray, black, olive
Effect of heat	Stable to charring
Effect of water	Swells and softens. Warps on drying. Not recommended.
Effect of mineral, animal, and vegetable oils	Very slight absorption
Specific gravity	1.2—1.5
Specific volume	18.5—23 in.^{3}/lb.
Tensile strength	8000—16000 lbs./in.^{2}
Breakdown voltage, 60 cycle, $\frac{1}{16}$ inch sample	175—500 volts/mil

* See section on synthetic rubbers.

PROPERTIES OF MATE-

PROPERTIES OF RE-

Type of brick	Chrome	No. 1 Fire clay	Fused alumina	Fused refractory
Typical composition, %	44 Cr_2O_3 16FeO 15MgO 15Al_2O_3 5SiO_2	42Al_2O_3 54SiO_2 2 Flux	90Al_2O_3 7 SiO_2 3 Flux	75 Al_2O_3 20 SiO_2 3.3 TiO_2
Fusion point, °F.	4000	3050	3500	3360
Load resistance, temp. °F. for 10% shrink at 25 lb.	2600	2700	2800	.....
Resistance to spalling in cycles	2	20	4	.....
Weight per standard 9 in. brick, lbs.	11.1	7.5	10	10
Porosity in %	.....	20–30	20	0.4
Specific heat (60–1200°F.)	0.20	0.23	0.20	0.23–0.255
Relative slag resistance				
Acid steel slag	Poor	Fair	Good	.....
Basic steel slag	Good	Poor	Good	.....
Mill scale	Good	Poor	Fair	.....
Coal ash slag	Fair	Fair	Good	.....
Approximate cost per thousand, dollars	250	35–40	1000	1000

ASBESTOS FIBER AND PORTLAND CEMENT

Property	Flat sheets	Corrugated sheets	Pipe	Impregnated material
Sizes	36x48, 42x48, 42x96, all ⅛ to 4 in. thick	42 in. Wide, 3-11 ft. long, ⅜ in. thick	2-36 in. diam. 0-225 lbs./in.^{2} pressure	Same as plain
Temp. limit, °F.	700	700	700	150
Density, lbs./ft.^{3}	125	125	125	128
Water permeability	Low	Low	Very low	Very low
Modulus of rupture, lbs./in.^{2} (Aver.)	3500	3000	.....	.....
Modulus of elasticity	1,500,000	1,500,000	2,000,000	1,500,000
Electrical resistance—Megohms per inch cube		.....	.....	4,000,000

FORMULAS OF THERMOSETTING MATERIALS

(14) Phenol-Formaldehyde

$$C_6H_5OH + HCHO \longrightarrow [—C_6H_2(OH)CH_2—]_n$$

Phenol — Formaldehyde — Durez, Resinox

(15) Phenol-Furfural

$$C_6H_5OH + C_4H_3O(CHO) \longrightarrow [—C_6H_3(OH)\cdot CH\cdot C_4HO=]_n$$

Phenol — Furfural — Durite

(16) Urea-Formaldehyde

$$CO(NH_2)_2 + HCHO \longrightarrow [—CH_2\cdot N\cdot CO\cdot NH—]_n$$

Urea — Formaldehyde — Plaskon, Beetle

(17) Melamine-Formaldehyde

$$H_2N\cdot CN \longrightarrow C_3H_3(NH_2)_3 + HCHO \longrightarrow [—NH\cdot C_3N_3:(NHCH_2—)_2]_n$$

Cyanamide — Melamine — Formaldehyde — Melmac, Resimene

(18) Polyester

$$(CHCO)_2O + (HOCH_2CH_2)_2O + C_6H_5CH:CH_2$$

Maleic anhydride — Diglycol — Styrene

$$\longrightarrow \left[\begin{array}{l} —CH—CH\cdot CH_2\cdot CH(C_6H_5)— \\ O:C\quad O:C\cdot O\cdot(CH_2)_2\cdot O\cdot(CH_2)_2\cdot O— \end{array}\right]_n$$

(19) Silicone Rubber

$$Cl_2Si(CH_3)_2 \longrightarrow (HO)_2Si(CH_3)_2 \longrightarrow [—Si(CH_3)_2\cdot O—]_n$$

Dimethylchlorosilane — Silastic

FORMULAS OF SYNTHETIC RUBBERS

Approximate proportions in parts by weight.

(a) GR-S

$$CH_2:CH\cdot CH:CH_2 + CH(C_6H_5):CH_2 \longrightarrow [—CH_2\cdot CH:CH\cdot CH_2\cdot CH(C_6H_5)\cdot CH_2—]_n$$

1,3-Butadiene 75 parts — Styrene 25 parts — GR-S

(b) Butene-Diene

$$CH_2:C(CH_3)_2 + CH_2:C(CH_3)\cdot CH:CH_2 \longrightarrow \left[—\left(CH_2\cdot\overset{CH_3}{\overset{|}{C}}—\right)_{90}—\overset{H}{\overset{|}{C}}\cdot\overset{CH_3}{\overset{|}{C}}:CH\cdot CH—\right]_n$$

Isobutene 98 parts — Diene 2 parts — Butyl

(c) Neoprene

$$CH_2:C(Cl)\cdot CH:CH_2 \longrightarrow [—CH_2\cdot C(Cl):CH\cdot CH_2—]_n$$

Chloroprene — Neoprene

(d) Acrylonitrile copolymers

$$CH_2:CH\cdot CN + CH_2:CH\cdot CH:CH_2 \longrightarrow [—CH_2\cdot CH:CH\cdot CH_2\cdot CH(CN)—]_n$$

Acrylonitrile — Butadiene — Hycar, Chemigum, Butaprene, Perbunan

Low	10-20 parts	60-80 parts
Medium	20-35 parts	
High	35 parts	

(e) Thiokol

$$Cl\cdot R\cdot Cl + Na_2S_4 \longrightarrow [—R—S_4—]_n$$

Dichloride — Sodium polysulfide — Thiokol

where R $—CH_2\cdot CH_2—$

or $—CH_2\cdot CH_2\cdot O\cdot CH_2\cdot CH_2—$

or $—CH_2\cdot CH_2\cdot O\cdot CH_2\cdot O\cdot CH_2\cdot CH_2—$

* The values were chosen as the most representative for each type. Considerable variation may occur since the properties of a molded article depend not only on the plastic used but on many other factors including conditions of forming and design of the molded part itself. Improvement of specific properties may often be accomplished by changes in formulation. Often improvement in one property may be accomplished at the expense of other properties.

* The values were chosen as the most representative for each type. Considerable variation may occur since properties of a rubber compound can be varied greatly by choice of fillers, softeners, resins, accelerators, condition of cure, and numerous other factors.

COMPOSITION AND PHYSICAL PROPERTIES OF ALLOYS

See also the table *Corrosion- and Heat-Resistant Alloys.*

The following table has the alloys arranged alphabetically according to the name of the element which predominates. The following abbreviations are employed: A, annealed; C, cold worked; AC, annealed and cold worked; H, hardened; HR, hot rolled. The ultimate strength is given in thousands of pounds per square inch.

Composition %	Trade Name	Sp. Gr.	M. P. °C.	Thermal Expansion $\times 10^6$	Ultimate Strength
Aluminum					
99.2Al	Aluminum 2S	2.71	660	23.94	12AC
95Al, 5Cu	Lynite, body alloy		650	26	
94Al, 4Cu, 0.5Mg, 0.5Mn, coated with					
99.7+Al	Alclad 17 ST	2.79	538-46	21.96	55
90Al, 10Mg	Magnalium	2.50	600	24	
70Al, 30Mg	Magnalium	2.00	435		
98Al, 1.25Mn	Aluminum Alloy 3S	2.74	640-55	23.04	16-31 AC
95Al, 5Si	Aluminum-silicon 43	2.58	577-630	21.96	19
53Bi, 32Pb, 15Sn	Eutectic fusible alloy		96		
52Bi, 40Pb, 8Cd	Eutectic fusible alloy		91.5		
50Bi, 27Pb, 13Sn,10Cd	Lipowitz alloy		70–2		
50Bi, 25Pb, 12.5Sn, 12.5Cd	Wood's metal	9.7	70–2		
40Bi, 40Pb, 20Sn	Bismuth solder		111		
Cerium					
70-3Ce, 17-24Zn, 1.6-6Fe, 0-2.4Al, Mn	Ignition pin alloy				
61Ce, 37Fe	Ignition pin alloy				
56Co, 34-40Cr, 9.2W, 1.2-2C, 0-1Fe	Stellite No. 2				
55Co,20-23Cr, 15-20W, 3-5Fe, 1.5-4C	Stellite No. 3				
40-80Co, 20-35Cr, 0-25W, 0.75-2.5C	Stellite	8.50	1150	14.99	
Copper					
99.9+Cu	Deoxidized copper	8.50	1082	17.71	32-55
99.9Cu, 0.01P	Deoxidized copper	8.91	1082	17.71	35-55
90Cu, 10Al	Aluminum bronze	7.6	1050	16.5	
90Cu, 9Al, 1Fe	Resistac	.....	1066		75
80-90Cu, 8-10Al, 6-7Fe	Ampco Metal	7.2	649		60-100
88-96Cu, 2.3-10.5Al, Fe, Sn	Aluminum bronze	7.5-8.2	1038-71		
47Cu, 33Au, 20Ag	6 Carat gold				
40Cu, 31Au, 19Ag, 10Pd	Palladium gold				
95Cu, 5Mn	Manganese bronze	8.8	1060		
82Cu, 15Mn, 3Ni	Manganin	8.5			
61Cu, 26Mn, 13Al	Magnetic alloy				
88.5Cu, 5Ni, 5Sn, 1.5Si	Barberite	8.8	1070		60
75Cu, 25Ni	Nickel coinage, U.S.A.				

COMPOSITION AND PHYSICAL PROPERTIES OF ALLOYS

Composition %	Trade Name	Sp. Gr.	M.P. °C.	Thermal Expansion $\times 10^6$	Ultimate Strength
Copper

*This alloy (Lipowitz's alloy) and many others can be alloyed with mercury to further reduce the melting point; after melting the alloy and removing the molten mass from the source of heat, the mercury is introduced and the mixture stirred with an iron rod. **CAUTION:** mercury vapors are poisonous.

CORROSION AND HEAT RESISTANT ALLOYS

ALLOY CASTING INSTITUTE STANDARD DESIGNATIONS AND CHEMICAL COMPOSITION RANGES FOR HEAT AND CORROSION RESISTANT CASTINGS

(Cast Stainless Steels, 1954)

Designations with the initial letter "C" indicate alloys generally used to resist corrosive attack at temperatures <1200°F (649°C); with the initial letter "H" to resist attack where the metal temperature is >1200°F. The second letter represents the nominal Cr-Ni type; the Ni increasing in amount from "A" to "X"; e.g., "F" stands for the 19% Cr-9% Ni, "K" for the 25% Cr-20% Ni, and "W" for the 12% Cr-60% Ni types. Numerals following the letters indicate the *maximum* carbon content of the corrosion resistant alloys; carbon content may also be designated in the heat resistant grades by following the letters with a numeral to indicate the *midpoint* of a ±0.10% carbon range. If special elements are included in the composition they are indicated by the addition of a letter to the symbol; e.g., "CF-8M" is an alloy for corrosion resistant service of the molybdenum-containing 19% Cr-9% Ni type with a maximum carbon content of 0.08%. In addition to the standard grades listed below, letters have been assigned to the nominal Cr-Ni contents for the following compositions which are produced in various modifications for special service: "M," 10% Cr-20% Ni; "N," 20% Cr-25% Ni; "P," 30% Cr-30% Ni; "S," 10% Cr-31% Ni.

AMERICAN IRON AND STEEL INSTITUTE STANDARD DESIGNATIONS AND CHEMICAL COMPOSITION RANGES OF STAINLESS AND HEAT RESISTING STEELS

(April 1955)

The chemical composition ranges given in the table are based on ladle analysis. The designations are in use throughout the Industry and serve as a definite means of identification for the different grade classifications.

The maximum phosphorus content of the "300" series, except Nos. 303 and 303 Se, is 0.045%. The maximum phosphorus content of the "400" series, except Nos. 416, 416 Se, and 430F, and of the "500" series is 0.040%. The maximum sulfur content for all type numbers, except Nos. 303, 303 Se, 416, 416 Se, 430F and 430F Se, is 0.030%.

ETCHING SOLUTIONS FOR FERROUS ALLOYS

Used to Show	Composition of etching solution	Remarks
For Macroscopic Examination		
Segregations	1 part conc. hydrochloric acid, HCl 1 part water	Use at 100 to 212° F. Etch for ½ hour or until defects are brought out.
Segregations	5 g picric acid, $HOC_6H_2(NO_2)_3$ 100 cc ethyl alcohol, C_2H_5OH	Etch for 4 to 5 hours.
Phosphorus segregations	10 g cuprous ammonium chloride, $CuCl{\cdot}NH_4Cl{\cdot}6H_2O$ 100 cc water	This solution is more easily prepared than are most copper chloride solutions.
Phosphorus segregations	10 g cupric chloride, $CuCl_2$ 40 g magnesium chloride, $MgCl_2$ 20 cc hydrochloric acid, HCl 180 cc water 1000 cc absolute alcohol, C_2H_5OH	Absolute methyl alcohol, CH_3OH, may be used in place of ethyl alcohol.
Variations in crystal structure, and segregations	20 g ammonium persulfate, $(NH_4)_2S_2O_8$ 100 cc distilled water	Use at room temperature. A very good reagent for the purpose indicated.
To reveal the structure of welds and to distinguish between steel and wrought	1 part conc. nitric acid, HNO_3 3 parts of water	Use at about 100° F.
For Microscopic Examination		
The general structure of normal iron and steel	4 g picric acid and 95 cc of absolute alcohol, or 5 g picric acid and 100 cc of	Keep bottle well stoppered when absolute alcohol is used.
The general structure of normal iron and steel	5 cc nitric acid, HNO_3 100 cc of ethyl alcohol, C_2H_5OH	For heat treated steels use a more dilute solution.
To establish the difference between hardened and normal steels	4 parts nitric acid, HNO_3 96 parts iso-amyl alcohol, $C_5H_{11}OH$	
Sorbitic and troostitic constituents	1 part of a 40% solution of nitric acid in acetic anhydride 1 part methyl alcohol, CH_3OH 1 part ethyl alcohol, C_2H_5OH 1 part iso-amyl alcohol, $C_5H_{11}OH$	Colors troostite and troosto-sorbite.

ETCHING SOLUTIONS FOR FERROUS ALLOYS

Used to show	Composition of etching solution	Remarks
Cementite and other carbides, and tungstites	2 g picric acid, $HOC_6H_2(NO_2)_3$ 24.5 g sodium hydroxide, NaOH 73.5 cc water	Use boiling for 5 or 10 minutes. Tungsten carbide is unaffected, but other carbides and tungstides are colored.
Structure of stainless steels	10 g ferric chloride, $FeCl_3$ 30 cc hydrochloric acid water to make total volume 120 cc	May be diluted, and applied gently with a piece of cotton. Time required is less than 30 seconds.
Structure of stainless steels	30 cc hydrochloric acid, HCl 10 cc nitric acid, HNO_3 80 cc glycerol (glycerine)	Use full strength for rapid work, but handle carefully.
Carbides and tungstides in high-speed and tungsten steels	10 g potassium ferricyanide, $K_3Fe(CN)_6$ 10 g potassium hydroxide, KOH 100 cc water	Use hot.
Structure of high-speed steel and tungsten carbide	10 cc commercial hydrogen peroxide, H_2O_2 20 cc of a 10% aqueous sodium hydroxide (NaOH) solution	Use fresh from 10 to 12 minutes. Tungsten carbide is darkened.
Structure of stellite, high-chrome steels, etc.	Use a low electric current through a solution of 0.5 g sodium hydroxide (NaOH) in 100 cc of water.	Use two 4 c.p. lamps in series on a 110-volt D. C. circuit. Cover the specimen with the solution; make contact with one wire at the side and dip the other with the solution moving so as to obtain a uniform etch.

ETCHING SOLUTIONS FOR NON-FERROUS ALLOYS

Metal or Alloy	Composition of etching solution	Remarks
Copper Base Alloys		
Copper or Cu-Al alloys	5 g copper-ammonium chloride 120 cc water Add conc. ammonium hydroxide until the precipitate which forms is redissolved, giving a clear blue color.	Etch from 30 to 60 seconds; this is a very good copper etch.
Copper, brasses, Cu-Al alloys, German silver	A 10% solution of ammonium persulfate, $(NH_4)_2S_2O_8$	Etch from 1 to 2 minutes. Keep the surface of the specimen free from grease.
Copper or brasses	10 cc hydrogen peroxide, H_2O_2 40 cc conc. ammonium hydroxide, NH_4OH	Apply with a swab to the surface of polished specimen. Rub briskly until mirror-like surface is obtained.

ETCHING SOLUTIONS FOR NON-FERROUS ALLOYS

Metal or Alloy	Composition of etching solution	Remarks
Copper Base Alloys		
Brasses (Used for copper products such as sheets, rods, etc.), Cu-Al alloys, German silver	15 cc of a saturated ferric chloride ($FeCl_3$) solution 30 cc concentrated hydrochloric acid, HCl 200 cc water	Use this solution after the ammoniacal peroxide solution above. Dip the specimen into this ferric chloride solution for a few seconds after following the directions above.
Cu-Al alloys	Nitric acid (HNO_3), sp. gr. 1.42	Time for etching is very short. It is difficult to control the intensity of the attack.
Aluminum and Light Alloys		
Al and Al alloys	0.5 to 20% hydrofluoric acid (HF) acid solutions. The aqueous or alcoholic solutions are used.	Etch for about 15 seconds. Remove the black deposit so formed by immersing for a short time in conc. nitric (HNO_3) acid. $CuAl_2$ and $FeAl_3$ are darkened by HF.
Aluminum	45 cc conc. hydrochloric acid, HCl 15 cc conc. nitric acid, HNO_3 15 cc hydrofluoric acid, HF 25 cc hot water	This etch generally requires only a few seconds.
Al alloys	10 cc conc. nitric acid, HNO_3 3 to 4 cc hydrofluoric acid, HF 86 to 87 cc hot water	
Al and Al alloys	10 to 20% aqueous sulfuric acid (H_2SO_4) solution	Heat to 160°F., immerse specimen for a few seconds, quench in cold water. $FeAl_3$ is stained black.
Al and Al alloys	10 cc conc. hydrofluoric acid, HF 15 cc conc. hydrochloric acid, HCl 90 cc water	Etch from 30 to 90 seconds. Reveals grain size very clearly.
Lead, Tin, Zinc and Their Alloys		
Used for zinc	6% chromic acid, 94% nitric acid	Add a few drops of this solution to 100 cc of water before using.
Tin alloys	2% alcoholic nitric acid solution	
Lead alloys	5% aqueous nitric acid solution	

ETCHING SOLUTIONS FOR NON-FERROUS ALLOYS

Metal or Alloy	Composition of etching solution	Remarks
Lead, Tin, Zinc and Their Alloys		
All "white metals"	Hydrochloric acid, either dilute or concentrated, depending upon the composition of the alloy. A 5% solution is best for an alloy rich in zinc.	When a concentrated solution is used, dip the specimen in the acid for a few seconds, wash carefully, and dry.
Alloys rich in zinc or cadmium	1 part iodine 3 parts potassium iodide, KI 10 parts water	
Alloys of lead, tin, antimony, bismuth, and anti-friction metals	5% aqueous solution of silver nitrate, $AgNO_3$	
Antimony and lead alloys, and babbit metal	10 g ferric chloride, $FeCl_3$ 30 cc hydrochloric acid, HCl, sp. gr. 1.19 120 cc water	A good etching solution for the metals named.
Miscellaneous Metals and Alloys		
Nickel and its alloys	50 cc of 70% nitric acid, HNO_3 50 cc of 50% acetic acid, $HC_2H_3O_2$	This is *Merica's solution.* It is very good for cast, cold drawn, and annealed nickel.
Nickel and its alloys	20 to 40 cc of nitric acid, HNO_3 30 to 40 cc of 75% acetic acid, $HC_2H_3O_2$ 30 to 40 cc acetone, $(CH_3)_2CO$	This solution is very similar in action to the one above.
Magnesium and its alloys	2% aqueous nitric acid solution	Etch for about 10 seconds.
Gold, silver, platinum, and other noble metals*	1 part nitric acid, HNO_3 5 parts hydrochloric acid, HCl 6 parts water	Use at about 60°F.
Dow metals (90-96% Mg, 4-12% Al, 0.1-0.3% Mn)	2% aqueous oxalic acid solution, $H_2C_2O_4$	Swab during etching. Rinse with water, then with alcohol, and dry with a blast of warm air.

* For Au-Cu and Au-Ag alloys it is better to saturate the etching solution with either sodium chloride or ammonium chloride.

SOLDERS AND FLUXES

Cf. Mebs and Roeser, *Natl. Bur. Standards, Cir.* **492** (1950).

Soft solders are used for joining metals having low melting points and they can be applied by simple means. They withstand considerable bending without fracture but they have low strength as compared with that of the metals usually joined. Compared with soft solders, hard solders have higher melting points and form joints of greater strength. There are three typical hard solders: (*a*) precious-metal; (*b*) ordinary-brazing; and (*c*) the aluminum-brazing solders consisting of special alloys of aluminum, proprietary in nature, which can be obtained from manufacturers of aluminum alloys.

Fluxes ("acid" fluxes) most commonly used for soft soldering metals other than aluminum are solutions or pastes containing zinc chloride or a mixture of zinc chloride with ammonium chloride. Where the last traces of such corrosive (acid) fluxes cannot be removed, rosin or rosin mixtures are used for ordinary purposes. Borax or mixtures of borax (75 to 25%) with boric acid are used as fluxes with hard solders. Many fluxes of a proprietary nature may contain in addition materials such as phosphorus and halogen salts, alkali bifluorides, and sodium cyanide. Proprietary fluxes which are satisfactory for aluminum can be obtained from suppliers of aluminum solders.

#, remainder is zinc. §, remainder is copper. M, maximum. m, minimum.
(1) Temperature range at which the alloy begins to melt and when completely molten.
(2) Federal specification QQ-S-551 (1932) and amendment 1 (1942).
(3) Designated in Soc. Auto. Eng. Handbook, 1948 edition.
(4) Designated in Am. Welding Soc. Handbook, 1942 edition.

PROPERTIES OF MATE-
THERMAL CONDUCTIVITIES

No.	Material	General composition	Commercial construction
1	Aerogel	Opacified silica	.....
2	Air	Still air	.....
3	Aluminum foil, crumpled	7 layers/2.5 inches	.....
4	Asbestos	.....	.....
5	" , paper, indented	26 laminations/inch	Pipe covering
6	" , paper	Corrugated air cell type	Pipe covering and sheets
7	" , paper, vitrified	Treated with vitrifying soln. and baked	Pipe covering and sheets
8	" , cement boards	.....	Rigid sheets
9	" fiber cement	Asbestos and clay	Cement
10	" fiber	Willowed asbestos, water-proofed	Filling for underground conduits
11	" millboards	Pressed asbestos	Rigid sheets
12	" sheets	.....	.....
13	" slate	.....	.....
14	Ashes, wood	.....	Filler
15	Asphalt	.....	.....
16	Bauxite, monohydrated	Molded with asbestos and clay	Pipe covering, bricks
17	Brick	Building brick	.....
18	" , alumina	92-99% Al_2O_3, fused	.....
19	" , alumina	65% Al_2O_3	.....
20	" , carbon	.....	.....
21	" , chrome	32% Cr_2O_3	.....
22	" , diatomaceous earth	Natural, across strata	.....
23	" , diatomaceous earth	Natural, parallel to strata	.....
24	" , diatomaceous earth	Molded and fired	.....
25	" , diatomaceous earth	High burn, large pores	.....
26	" , diatomaceous earth	With clay, molded and fired	.....
27	" , fire clay	Missouri clay	.....
28	" , insulating	Kaolin brick	.....

STANDARD CALIBRATION TABLES FOR THERMOCOUPLES

The following tables represent arbitrary reference curves which show fairly well the relation between emf and temperature and consequently should be used with an appropriate correction curve which must be determined for any individual thermocouple by means of a calibration at three or more fixed temperature points. Such a correction curve is constructed by plotting ΔE the difference between the observed emf at a known temperature and the emf for this same temperature (as read from the table) against the standard emf given in the table. The corrected emf for any temperature is then obtained by subtracting algebraically ΔE as read from the correction curve from the observed emf, before converting the latter into a temperature as read from the table. The tables which follow are for a fixed (or cold) junction maintained at 0°C. If this fixed junction is not at 0°C. but at some other temperature which is very near to 0°C. a correction should be applied as follows: $E_h = E_o + E$ where E_o is the observed emf, E is the emf corresponding to the temperature of the fixed junction and E_h is the desired emf corrected for the temperature at which the fixed junction is being maintained. In the tables which follow the emf values are expressed in absolute millivolts (=0.99967 international millivolts, U. S.) and the temperatures in degrees Celsius (centigrade) on the International Temperature Scale of 1948. References: National Bureau Standards *Circular 561 (1955)*; *Jour. Res. Natl. Bur. FIXED POINTS FOR THERMOMETER CALIBRATION

INTERNATIONAL TEMPERATURE SCALE OF 1948

This temperature scale is the revision of the International Temperature Scale first adopted in 1927. It is designed to conform as nearly as practicable to the thermodynamic temperature scale as now known. It is based upon six fixed and reproducible equilibrium temperatures to which numerical values have been assigned and upon specified interpolation formulas relating temperature to the indications of specified measuring instruments. The specified measuring instruments are the standard platinum resistance thermometer, the standard platinum platinum-rhodium thermocouple and the optical pyrometer. For further definitions and recommendations as to apparatus and procedures the reader should consult the text of the International Temperature Scale, *Jour. Res. Natl. Bur. Stds.*, **42**, 209 (1949).

In addition to the six fundamental and primary fixed points, certain other (secondary) fixed points are available and may be used for various purposes. The values of these secondary, fixed-point temperatures are not defined but have been derived from temperature determinations with standard instruments. The temperatures assigned to the six primary fixed-points and some of the secondary fixed-points are listed in the following table.

FIXED POINTS FOR THERMOMETER CALIBRATION

PRIMARY AND SECONDARY FIXED POINTS

Under the pressure of 1 standard atmosphere (except for the triple points).

Temperature of	In °C (Int. 1948)	Pressure corrections and conditions
Equilibrium between liquid oxygen and its vapor. Oxygen point.	−182.970	Primary fixed point. $+0.01254(P_{mm}-760)-0.000006(P_{mm}-760)^2$
Equilibrium between solid carbon dioxide and its vapor.	−78.5	$+0.01595(P_{mm}-760)-0.000011(P_{mm}-760)^2$
Freezing mercury	−38 87	....
Equilibrium between ice and air-saturated vapor. Ice point.	0	Fundamental fixed point.
Equilibrium between ice, water and its vapor. Triple point.	+0.0100	Recommended for measurements of the highest precision.
Equilibrium between liquid water and its vapor.	100	Fundamental fixed point. $+0.03686(P_{mm}-760)-0.000020(P_{mm}-760)^2$
Equilibrium between solid benzoic acid, its liquid and vapor. Triple point.	122 36	.....
Freezing tin.	231.9	.....
Freezing cadmium.	320 9	.....
Freezing lead.	327.3	.....
Equilibrium between liquid mercury and its vapor.	356 58	$+0\ 07309(P_{mm}-760)-0.000040(P_{mm}-760)^2$
Freezing zinc.	419 5	.....
Equilibrium between liquid sulfur and its vapor. Sulfur point.	444 600	Primary fixed point. $+0.09080(P_{mm}-760)-0.000048(P_{mm}-760)^2$
Freezing antimony.	630 5	.....
Freezing aluminum.	660.1	.....
Equlibrium between solid silver and its liquid. Silver point.	960.8	Primary fixed point.
Equilibrium between solid gold and its liquid. Gold point.	1063.0	Primary fixed point.
Freezing copper.	1083	In a reducing atmosphere.
Freezing nickel.	1453	.....
Freezing cobalt.	1492	.....
Freezing palladium.	1552	.....
Freezing platinum.	1769	.....
Freezing rhodium	1960	.....
Freezing iridium.	2443	.....
Melting tungsten.	3380	.....

TEMPERATURE REFERENCE POINTS FOR CALIBRATION OF LABORATORY INSTRUMENTS

The following compilation of fixed temperature points is based upon constants of certain organic compounds which have been measured with sufficient care to warrant their acceptance for *fairly close approximations* of temperature readings. The values are for *carefully* purified compounds and should *not* be applied except to material which has been carefully prepared and purified, to a constant set of physical properties, by repeated fractional distillations and/or freezings. The list was compiled by

FIXED POINTS FOR THERMOMETER CALIBRATION

making a selection from the compounds listed in Timmermans' *PHYSICO-CHEMICAL CONSTANTS OF PURE ORGANIC COMPOUNDS*, Elsevier Publishing Co., Inc., New York (1950).

Abbreviations: *B*, boiling point at 760 mm of mercury pressure; *F*, freezing point; *M*, melting point.

Substance	Point	°C	Pressure corrections
iso-Pentane	F	−159.9	.....
Methylcyclohexane	F	−126.6	.....

CHANGES IN CALIBRATION

Tests of a liquid-in-glass thermometer consist of comparisons of readings at an adequate number of points on its scale, usually at intervals from 40 to 100 divisions, with those on a standard instrument. Such a standard instrument may be either a standard platinum resistance thermometer or a suitable mercury-in-glass thermometer which has been standardized on the International Temperature Scale.

* Slow melting to allow for crystalline transition from a metastable crystalline form which melts at −123.4°C.

CORRECTION FACTORS FOR MERCURY-IN-GLASS THERMOMETERS

Tests may also be made at the ice and steam points and a number of secondary fixed points if the equipment for attaining the temperatures of the fixed points is available.

Thermometers are subject to changes with time and use primarily as a result of changes in the volume of the bulb. For well-annealed thermometers, not subject to excessively high temperatures, bulb changes are small. After a thermometer has been heated, the bulb does not at once return to its original volume but remains somewhat larger thus temporarily lowering the readings; and if a thermometer is kept at a high temperature for long periods the ice point and the boiling point may be permanently lowered. All such changes may be determined by making a test at some reference point and changing all readings by the amount of the observed change.

Use of a thermometer at pressures differing appreciably from those prevailing during test will yield different readings. A greater pressure on the bulb will result in higher readings and a lesser pressure in lower readings. Such changes for cylindrical bulbs having a diameter of from 5 to 7 mm are of the order of 0.1°C (0.2°F) per atmosphere of pressure.

See also section on *Correction for Emergent Stem.*

CORRECTION FOR EMERGENT STEM OF LIQUID-IN-GLASS THERMOMETERS

When a thermometer which has been standardized for total immersion is used with a part of the liquid column at a temperature below that of the bulb, the reading is low and a correction must be applied. For this correction the following formula is employed:

$$T_c = T_o + f \times l \times (T_o - T_m)$$

where T_c = corrected temperature

T_o = observed temperature

l = length of column in degrees above the surface of the liquid the temperature of which is being taken

T_m = mean temperature of mercury (or other thermometer liquid) column; i. e., the temperature of the middle point of the mercury (or other liquid) column as read from another thermometer

f = correction factor as given in the table below. In calculating the emergent stem correction for thermometers containing organic liquids (alcohol, pentane, toluene) it is sufficient to use the approximate value, $f = 0.001$. In such thermometers the value of f is practically independent of the kind of glass.

FUSING POINTS AND COMPO-

Information furnished by The Standard Pyrometric Cone Co., Columbus, O.

The fusing point values given in the table below have only a relative or theoretical value, being a summarized outline of determinations made by the U. S. Bu. of Standards (*Jour. Am. Ceramic Soc.* 9, 70 (1926) and are approximate values given to the nearest 5°C from the average of many determinations; therefore, between any two cones there may be an error of ±5°C. The values apply only when the cones are heated in kilns where the gases are normally oxidizing and free from oxides of sulfur. If the cones show a hardening of the surface ("skin effect") because of exposure to kiln gases with lack of oxygen, small corrections must be made. Kilns rich in sulfur oxides because of the fuel employed or wares which give off sulfur dioxide may cause appreciable variation in fusing points. Fusion of a cone is said to have been attained when the tip touches the base upon which the cone has been set.

From what has been stated above it is evident that pyrometric cones are not intended as a means of measuring temperature. **Their sole purpose is to serve as a guide in the firing of ceramic wares.** Since both the cones and the wares are composed of ceramic materials they are similarly affected by variable conditions within the kiln, and are thus a more reliable guide for firing than any device which indicates only one of these variables, namely the temperature. When cones behave erratically, they indicate abnormal kiln conditions which in many instances affect the

Cone Number	Fusion Temperature When Heated: Slowly 20°C. per hr. °C.	Slowly 20°C. per hr. °F.	Rapidly 150°C. per hr. °C.	Rapidly 150°C. per hr. °F.	Color Scale	Heat Treatment Range

SITION OF PYROMETRIC CONES

ware unfavorably. Cones in series should go over seriatim otherwise something is wrong with the firing conditions. Although fusion temperatures of cones are affected by sulfur oxides and since the majority of ceramic wares are fired with sulfurous fuel (or the ware itself contains sulfides or sulfates), nevertheless it does not follow that cones are not satisfactory under these conditions. A factory selects by trial a cone which has a satisfactory end point for its ware and since all the cones used by it go through this sulfur treatment, so far as that factory is concerned all have practically the same relative end points.

Series Classification—The *Soft* or *Decorating* series begins with No. 022, softening at dull red heat and runs through to No. 011, the temperature range between numbers being approximately 30°C or 54°F. Of these, No. 017 represents the temperature usually employed for liquid bright gold, and most overglaze colors for pottery and glass are made to work best at this heat. These cones contain lead and are quite sensitive to reducing gases; they should be used only in muffle kilns or where they cannot come in contact with flames. The *Low* temperature series includes Nos. 010 to 01 and is used chiefly for firing red burning clay products and soft glazes. The *Intermediate* temperature series includes Nos. 1 to 20 and is used chiefly for firing buff and white clay products and hard glazes. The *High* temperature series includes Nos. 23 to 42 and is used chiefly for firing and testing refractory materials.

A SHORT GLOSSARY OF CERAMIC TERMS

Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL
of The Harshaw Chemical Co., Cleveland, Ohio.

Albany slip, a natural glaze burning brown to black.

Anneal, to relieve strains by heat.

Bait, a device for grabbing glass prior to drawing.

Belleek, a soft translucent ivory porcelain, usually very thin.

Bisque (body), unglazed, fired clayware.

Blunging, a mechanical mixing of clay or slip with water, and separating from sand and pebbles; washing.

Body stain, cf. *ceramic colors.*

Bone china, a china made with a body containing bone ash.

Casing, coating one piece of glass with another while hot.

Casting (pottery), forming pottery by pouring slip into a porous mold; e. g. in plaster of Paris.

Casting (glass), pouring glass from a crucible to a plate; flat glass.

Ceramic, clay or siliceous products hardened by the action of heat.

Ceramic colors—

Body stains, colors used in the body.

Engobe, colors used in a slip over a body or between the body and the glaze.

Glass colors, fusible colors fired over glassware.

Glaze stains, colors used in the glaze.

Lustres, organic solutions of metals which when applied to pottery and fired give iridescent metallic films.

Overglaze, fusible colors fired over glazed ware.

Underglaze, color applied over the body before glazing.

China, translucent vitrified glazed opaque ware, body usually vitrified before glazing.

Cloisonne (enamel), colored vitrified enamel on a metal base in which the different colors are separated by metal strips.

Cloisonne ware, colored pottery in which the different colored glazes are separated by a narrow line of hard black glaze.

Colors, cf. *ceramic colors.*

Cones, pyramid shaped fusible bodies of progressive softening order, employed as a guide in determining the finishing point of the ceramic kiln.

Continuous furnace or lehr, a furnace or lehr in which the firing takes place in a continuous operation.

Copper heads, copper colored spots in ground coat enamel.

Cords, variations in the density of glass.

Crackle (Craquelle), cracks in glaze due to crazing and which are sometimes produced intentionally.

Cranny, the sharp edge of a marver.

Crawl, a grouping of glaze, slip, or enamel during drying or firing, generally due to fineness of particles.

Crazing, the development of fine cracks caused by excessive contraction of a glaze or enamel.

Decalcomania, designs produced on enamels, pottery, or glass by transferring to them vitreous colors on paper and then firing.

Deflocculation, a dispersion of particles and agglomerates resulting in thinning the suspension; an excess of electrolytes; long; sol.

Devitrification, the crystallization of a vitreous material.

Dipping, an application of glaze or enamel by immersion and allowing the excess to drain off.

Draw, absorption of glaze by an unglazed surface nearby during firing.

Dunting, splitting of claywares due to silica inversion.

Egg shell, incomplete vitrification; cf. *devitrification.*

Enamel, a fusible vitreous coating for metals or claywares at low temperatures; an opaque coating.

Enamel frit, cf. *frit.*

Encaustic tile, a variety of tile having an inlaid design of a different color from that of the body of the tile; the term is now sometimes used to designate any dry pressed tile with a colored slip.

Engobe, cf. *ceramic colors.*

Faience, a general term covering "colored clay bodies glazed"; named after the town of Faenza, Italy.

Fining, removing small gas bubbles from molten glass; planing.

Firing racks, refractory racks or boxes for holding ware while firing.

Fishscaling, small fish-scale shaped chips jumping or chipping from enamel.

Flashing, coating a piece of glass with

A SHORT GLOSSARY OF CERAMIC TERMS

a thin layer of colored glass while hot.

Flocculation, the agglomeration of particles by the addition of electrolytes to give a proper consistency for dipping, casting, or spraying, setting-up; short; thickening.

Flux, a material or mixture having a low melting point; the first to fuse at a definite temperature.

Frit, any fused substance or mixture quenched; enamel frit; glaze frit.

Gathering, the collecting of glass on a blow-pipe.

Glass colors, cf. *ceramic colors.*

Glaze, vitrifiable coating for brick, bisque, porcelain, or pottery, or stoneware body.

Glaze frit, cf. *frit.*

Glaze stain, cf. *ceramic colors.*

Glory hole, a furnace for reheating

Glost, a term applied to glazed ware.

Glost kiln, a kiln for firing glaze.

Graining, the application and firing of a net work of one colored enamel or glaze over another colored enamel or glaze to imitate a natural wood or marble finish.

Green ware, formed but unfired pottery.

Grog, crushed bisque fire-brick, saggers, crucibles, or calcined clay.

Hacking, a stacking of claywares without the aid of stilts or saggers.

Hairlines, the fine lines appearing in fired enamel.

Intermittent kiln or lehr, a furnace or lehr that is loaded, fired, allowed to cool and unloaded; intermittent charges.

Jacks, cf. *stilts.*

Jigger, a machine for shaping pottery by means of a rotating mold and a profile tool.

Jumpers, small chips of enamel that jump from finished surface.

Kiln, a furnace or oven for firing pottery.

Lehr, a furnace for annealing or decorating glass.

Lustres, cf. *ceramic colors.*

Majolica, a rather general term for a colored, enameled, clay body; named after the Island of Majorca.

Marver, a polished stone or steel plate for working glass while blowing.

Monkey pots. small crucibles for experimental glass melts.

Mosaic, the union of pieces of colored stone, tile, etc. to form an artistic design, laid in metal, cement, etc.

Muffle furnace or kiln, a furnace or kiln so constructed that the space in which the ware is fired does not come in contact with fire or furnace gases.

Overglaze, cf. *ceramic colors.*

Parison, glass on the blow-pipe ready for final blowing.

Pin, cf. *stilts.*

Pin holes, holes left by the bursting of a blister during firing.

Planing, cf. *fining.*

Porcelain, a vitrified ware, generally translucent, made by one firing only.

Pot, a container for smelting.

Potters' wheel, a wheel for rotating plastic clay in forming ware by hand.

Pottery, a term commonly used to include all articles made of clay, or clay and mineral mixtures, and hardened by fire; in present usage the term does not include structural, refractory, or glass wares, or insulators.

Pugging, the intimate wet mixing of body constituents.

Punty, a tool upon which glass shapes are handled.

Pyrometric cone, cf. *cones.*

Refractory, having resistance to melting or fusion; a ware that does not fuse under 1500°C.

Saggers, refractory containers in which pottery is stacked for firing.

Seeds, the small bubbles in glass.

Seger cones, cf. *cones.*

Semi-vitreous china, semi-porous china.

Setters, a refractory support in which chinaware, tile, etc. are placed for firing. This ware is supported on its own base or its contour rests on sand, no stilts being used.

Setting-up, cf. *flocculation.*

Sherds (shords), broken saggers and bisque.

Shiners, shiny spots in enamel caused by fish-scaling or jumpers.

Shivering, a glaze or enamel expanding excessively on firing; chips.

Shords, cf. *sherds.*

Short, cf. *flocculation.*

Slip, a siliceous material (clay, glaze, engobe, or enamel) in aqueous suspension.

Slushing, the application of a heavy-bodied enamel or glaze by dipping and shaking off the excess.

Spalling, a disintegration on the sur-

A SHORT GLOSSARY OF CERAMIC TERMS

face of refractories, due to continued expansion and contraction, or to the formation of salts and the swelling of salts in service.

Spitout, a glaze defect conceded to be due to moisture in the body and which appears on refiring to the decorating temperature.

Spurs, cf. *stilts.*

Stilts, refractory pieces for supporting or separating ware in saggers during burning; various shapes are known as pins, jacks, spurs, or thimbles, etc.

Stones, refractory lumps in glass.

Tank, a furnace for smelting glass.

Tearing, cracks appearing in enamel during drying.

Terracotta, buff burned porous clay-ware used for interior and exterior decoration; sometimes glazed in colors.

Thickening, cf. flocculation.

Thimbles, cf. *stilts.*

Throwing, hand-forming pottery on a potter's wheel.

Tile, a fired clay body, white or colored, glazed or unglazed, porous or vitrified, in structural shapes; varieties are named according to method of manufacture and use; e.g. drain, encaustic, floor, hollow, mosaic, quarry, wall, etc.

Underglaze, cf. *ceramic colors.*

Watermark, discoloration of enameled or glazed ware after firing caused by an accumulation of soluble salts during drying.

COMMONLY USED CERAMIC MATERIALS *

Trade Name, Formula and % Yield Weight

Material	Formula	Form. Wt.	% Yield Weight
Adularia	$K_2O \cdot Al_2O_3 \cdot 6SiO_2$	556.49	K_2O 16.92, Al_2O_3 18.31, SiO_2 64.75
Albite	$Na_2O \cdot Al_2O_3 \cdot 6SiO_2$	524.29	Na_2O 11.82, Al_2O_3 19.44, SiO_2 68.73
Alum (ammonium)	$Al_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$	906.64	Al_2O_3 11.24
Alum (potassium)	$Al_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$	948.76	K_2O 9.93, Al_2O_3 10.75
Alum (sodium)	$Al_2(SO_4)_3 \cdot Na_2SO_4 \cdot 24H_2O$	916.56	Na_2O 6.76, Al_2O_3 11.12
Andalusite	$Al_2O_3 \cdot SiO_2$	162.00	Al_2O_3 62.93, SiO_2 37.07
Anorthite	$CaO \cdot Al_2O_3 \cdot 2SiO_2$	278.14	CaO 20.16, Al_2O_3 36.65, SiO_2 43.19
Apatite	$(CaF)\,Ca_4(PO_4)_3 \pm Cl$	.....	Variable
Barium carbonate	$BaCO_3$	197.37	BaO 77.70
Barytes	$BaSO_4$	233.42	BaO 65.70
Bauxite	$Al_2O_3 \cdot 2H_2O$	137.97	Al_2O_3 73.88
Beryl	$3BeO \cdot Al_2O_3 \cdot 6SiO_2$	537.36	BeO 13.97, Al_2O_3 18.97, SiO_2 67.06
Blanc-fixe	$BaSO_4$	233.42	BaO 65.70
Blue vitriol	$CuSO_4 \cdot 5H_2O$	249.69	CuO 31.86, Cu_2O 28.66
Borax	$Na_2B_4O_7 \cdot 10H_2O$	381.43	B_2O_3 36.52, Na_2O 16.25
Borax (anhyd.)	$Na_2B_4O_7$	201.27	B_2O_3 69.20, Na_2O 30.80
Boric acid	H_3BO_3	61.84	B_2O_3 56.30
Calcite	$CaCO_3$	100.09	CaO 56.03
Celestite	$SrSO_4$	183.69	SrO 56.42
Chile niter	$NaNO_3$	85.01	Na_2O 36.46
China clay	$Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$	258 09	Al_2O_3 39.50, SiO_2 46.54
Chromite	$FeO \cdot Cr_2O_3$	223.87	FeO 32.09, Cr_2O_3 67.91
Cobalt carbonate	$CoCO_3$	118.95	CoO 63.00
Cobalt hydrate	$Co(OH)_2$	92.96	CoO 80.61
Cobalt sulfate	$CoSO_4 \cdot 7H_2O$	281.11	CoO 26.66
Cobalto-cobaltic oxide	Co_3O_4	240.82	CoO 93.36
Colemanite	$2CaO \cdot 3B_2O_3 \cdot 5H_2O$	411.16	CaO 27.28, B_2O_3 50.81
Copper carbonate (basic)	$CuCO_3 \cdot Cu(OH)_2$	221.11	CuO 71.95, Cu_2O 64 71
Copper sulfate	$CuSO_4 \cdot 5H_2O$	249.69	CuO 31.86, Cu_2O 28.66
Copperas	$FeSO_4 \cdot 7H_2O$	278.03	Fe_2O_3 28.72
Cryolite	$3NaF \cdot AlF_3$	209.96	Na_2O 44.29, Al_2O_3 24.28, F 54.30
Cyanite	$Al_2O_3 \cdot SiO_2$	162.00	Al_2O_3 62.93, SiO_2 37.07
Diaspore	$Al_2O_3 \cdot H_2O$	119.96	Al_2O_3 84.98
Diopside	$CaO \cdot MgO \cdot 2SiO_2$	216.52	CaO 25.90, MgO 18.62, SiO_2 55.48
Dolomite	$CaCO_3 \cdot MgCO_3$	184.42	CaO 30.41, MgO 21.86
English chalk	$CaCO_3$	100.09	CaO 56.03
Epsom salts	$MgSO_4 \cdot 7H_2O$	246.50	MgO 16 36
Fluorite (fluorspar)	CaF_2	78.08	CaO 71.82, F 48.67
French chalk	$3MgO \cdot 4SiO_2 \cdot H_2O$	379.22	MgO 31.90, SiO_2 63.35
Gibbsite	$Al_2O_3\,3H_2O$	155.99	Al_2O_3 65.35
Gypsum	$CaSO_4 \cdot 2H_2O$	172.18	CaO 32.57
Ilmenite	$FeO \cdot TiO_2$	151.75	FeO 47.35, TiO_2 52.65
Lead chromate	$PbCrO_4$	323.22	PbO 69.06, Cr_2O_3 23.52
Lead disilicate	$PbO \cdot 2SiO_2$	343.33	PbO 65.01, SiO_2 34.99
Lead oxide (red)	Pb_3O_4	685.63	PbO 97.67
Leucite	$K_2O \cdot Al_2O_3 \cdot 4SiO_2$	436.37	K_2O 21.59, Al_2O_3 23.36, SiO_2 55.05
Lithium carbonate	Li_2CO_3	73.89	Li_2O 40.44
Limestone	$CaCO_3$	100.09	CaO 56.03
Limonite	$2Fe_2O_3 \cdot 3H_2O$	373.45	Fe_2O_3 85.53
Magnesite	$MgCO_3$	84.33	MgO 47.81
Magnetite	Fe_3O_4	231.55	Fe_2O_3 103.45
Manganese carbonate	$MnCO_3$	114.94	MnO 61.71
Manganese sulfate	$MnSO_4 \cdot 4H_2O$	223.05	MnO 31.80
Marble	$CaCO_3$	100.09	CaO 56.03
Marcasite	FeS_2	119.97	Fe_2O_3 66.56
Mullite	$3Al_2O_3 \cdot 2SiO_2$	425.94	Al_2O_3 71.80, SiO_2 28.20
Nickel carbonate	$NiCO_3$	118.70	NiO 62.92
Nickel sulfate	$NiSO_4 \cdot 6H_2O$	262.85	NiO 28.42
Niter	KNO_3	101.10	K_2O 46.58
Orthoclase	$K_2O \cdot Al_2O_3 \cdot 6SiO_2$	556.49	K_2O 16.92, Al_2O_3 18.31, SiO_2 64.75
Pearl ash	K_2CO_3	138.20	K_2O 68.16
Plaster of Paris	$CaSO_4 \cdot \frac{1}{2}H_2O$	145.15	CaO 38.64

* Commonly used materials having approximately 100% yield are not listed.

COMMONLY USED CERAMIC MATERIALS

Material	Formula	Form. Wt.	% Yield Weight
Pyrolusite	MnO_2	86.93	MnO 81.59
Potassium dichromate	$K_2Cr_2O_7$	294.21	K_2O 32.02, Cr_2O_3 51.67
Tungstic acid	H_2WO_4	249.94	WO_3 92.79
Siderite	$FeCO_3$	115.86	Fe_2O_3 68.92
Soda ash	Na_2CO_3	106.00	Na_2O 58.48
Sodium dichromate	$Na_2Cr_2O_7 \cdot 2H_2O$	298.05	Na_2O 20.80, Cr_2O_3 51.00
Sodium nitrate	$NaNO_3$	85.01	Na_2O 36.46
Vanadate (ammonium, meta)	NH_4VO_3	116.99	V_2O_5 77.74
White lead	$2PbCO_3 \cdot Pb(OH)_2$	775.67	PbO 86.33
Willemite	$2ZnO \cdot SiO_2$	222.82	ZnO 73 05, SiO_2 26.95
Witherite	$BaCO_3$	197.37	BaO 77.70
Wallastonite	$CaO \cdot SiO_2$	116.14	CaO 48.29, SiO_2 51.71
Zircon	$ZrO_2 \cdot SiO_2$	183.28	ZrO_2 67.23, SiO_2 32.77

MELTING POINTS OF SOME COMPOUNDS IN COMMON USE IN CERAMICS

Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL
of The Harshaw Chemical Co., Cleveland, Ohio.

The compounds in the table below are arranged according to increasing melting points. The melting points are values selected from those reported in the *International Critical Tables* or in the *Jour. Amer. Ceramic Soc.* The values followed by an E are for eutectics.

Melting Point °C.	Formula
415 E	$77.6PbO, 6.1B_2O_3, 16.3SiO_2$
532 E	$88.0PbO, 12.0SiO_2$
570 E	$24.2Na_2O, 35.2B_2O_3, 40.6SiO_2$
650 E	$60.8PbO, 7.1Al_2O_3, 31.45SiO_2$
655 E	$23.7K_2O, 37.2B_2O_3, 39.1SiO_2$
746±10	$2PbO \cdot SiO_2$
750 E	$76.5BaO, 23.5B_2O_3$
766±10	$PbO \cdot SiO_2$
780 E	$55.0K_2O, 45.0SiO_2$
800 E	$50K_2O \cdot B_2O_3, 50Na_2O \cdot B_2O_3$
800 E	$17.5Na_2O, 5.4Al_2O_3, 77.1SiO_2$
830 E	$51.5Na_2O, 48.5SiO_2$
860 E	$18.4Na_2O, 81.6SiO_2$
870 E	$17.4K_2O, 5.2Al_2O_3, 77.4SiO_2$
874±2	$Na_2O \cdot 2SiO_2$
880E	$17.5K_2O, 82.5SiO_2$
888±10	PbO
948	$Li_2O \cdot SiO_2$
976	$K_2O \cdot SiO_2$

Melting Point °C.	Formula
980	$K_2O \cdot 2TiO_2$
995 E	$35CaO, 65B_2O_3$
1010	$2Li_2O \cdot SiO_2$
1041	$K_2O \cdot 2SiO_2$
1070 E	$47.5CaO, 52.5B_2O_3$
1088±2	$Na_2O \cdot SiO_2$
1100±10	$Na_2O \cdot Al_2O_3 \cdot 6SiO_2$
1157 E	84.3 albite, 15.7 CaO
Cone 3 E	71.5 feldspar, 8.6 $CaCO_3$, 7.7 kaolin, 12.2 flint
Cone 4 E	42.1 potash feldspar, 17.7 $CaCO_3$, 13.0 hydrous kaolin, 27.2 flint
1242±2	$CdO \cdot SiO_2$
Cone 6 E	69 albite, 29 microcline
Cone 6 E	$35\text{-}40BaO, 10.0Al_2O_3, 50\text{-}55SiO_2$
1248±5	$Na_2O \cdot Al_2O_3$; nephelite
Cone 7 E	$67.0(Al_2O_3 \cdot 2SiO_2), 33.0CaO$
Cone 8 E	90.0 potash feldspar, 10.0 kaolin
1261 E	98.3 orthoclase, 1.7 CaO

MELTING POINTS OF SOME COMPOUNDS IN COMMON USE IN CERAMICS

Melting Point °C.	Formula
1271 E	98.6 orthoclase, 1.4 MgO
1273±5	$MnO_2 \cdot SiO_2$
1284±5	$Na_2O \cdot 2CaO \cdot 3SiO_2$
Cone 9 E	90.0 microcline, 10.0 quartz
Cone 10 E	74.4 ($Al_2O_3 \cdot SiO_2$), 25.6 CaO
Cone 10 E	30 MgO, 30 kaolin, 40 quartz
Cone 10 E	31 MgO, 13 Al_2O_3, 56 SiO_2
d1355±5	$3CaO \cdot Al_2O_3 \cdot SiO_2$
Cone 12 E	20.0 MgO, 20.0 Al_2O_3, 60.0 SiO_2
Cone 12-13 E	50 ZnO, 20 Al_2O_3, 30 SiO_2
1358	46.5 SrO, 53.5 SiO_2
1360 E	50.8 ZnO, 14.45 Al_2O_3, 35.75 SiO_2
1374	47.0 BaO, 53.0 SiO_2
1388±5	$Li_2O \cdot Al_2O_3 \cdot 2SiO_2$
1391±2	$CaO \cdot MgO \cdot 2SiO_2$
1400±3	$Li_2O \cdot Al_2O_3 \cdot 4SiO_2$
1436	37.0 CaO, 63.0 SiO_2
1437	65.0 BaO, 35.0 SiO_2

COEFFICIENTS OF CUBICAL EXPANSION FOR VARIOUS SOLIDS

The following are average values over the range from room temperature to the melting point expressed in change of volume per unit volume per degree Centigrade. The values for those substances preceded by a dagger (†) are values used in commercial practice; values for the other substances listed are those determined by Winkelmann and Schott, and Mayer and Havas. See also the table *Coefficients of Cubical Expansion for Liquids and Solutions.*

Substance	Coef. $\times 10^7$

BALL MILL SPEEDS

For the mathematics of the ball mill, see E. W. Davis, *Am. Inst. Min. and Met. Eng.* Vol. 61 (1920), and Haultain and Dyer, *Canadian Inst. Min. and Met.*, June 1922.

Diameters being equal the efficient speed of a ball mill depends upon the size and amount of the pebbles or balls, slippage between the lining of the mill and the charge (consistency), and the size of the charge.

In general practice the ball mill is first half filled with balls or pebbles, and then half as much enamel or glaze is added, and the required water if it is to be wet ground.

The speeds in the table given below are an average covering a large variety of materials and conditions.

Inside Diameter of Ball Mill in Feet	Speed of Ball Mill in RPM*
8.0	12 to 14
7.5	16 to 18
6.0	17 to 20
5.0	20 to 23
4.5	22 to 24
4.0	23 to 27

Inside Diameter of Ball Mill in Feet	Speed of Ball Mill in RPM*
3.5	25 to 28
3.0	26 to 30
2.5	30 to 38
2.0	35 to 40
1.5	40 to 53
1.0	42 to 55
Laboratory mills	50 to 85

*For dry mills use the higher values.

FORMULAS FOR CALCULATING PHYSICAL PROPERTIES OF CERAMIC MATERIALS

Reprinted from 1928 *Standards Report Amer. Ceramic Society*, by permission.

1. DETERMINATION OF WATER IN CERAMIC MATERIALS

Dry a 200 gram sample to constant weight at 110-50°C.

$$\% H_2O = \frac{W-D}{W} \times 100$$

W = weight of material received
D = weight of material after drying to constant weight

2. DETERMINATION OF TOTAL LINEAR DRY AND FIRED SHRINKAGE

Green bar size 2½″×4½″×9″; gauge marks 8″ apart
Fire to 1400°C. in not less than 5 hrs.; natural cooling

$$\% \text{ Shrinkage} = \frac{Lw-Lb}{Lw} \times 100$$

Lw = length of specimen in plastic state
Lb = length of specimen after firing to 1400°C.

3. DETERMINATION OF WATER OF PLASTICITY

$$T = \frac{Wp-Wd}{Wd} \times 100$$

T = % water of plasticity
Wp = weight of plastic test piece
Wd = weight of dry test piece

4. DETERMINATION OF SHRINKAGE WATER

$$t_1 = \frac{Vp-Vd}{Wd} \times 100$$

t_1 = % shrinkage water

Vp = plastic volume in cc.
Vd = dry volume in cc.
Wd = dry weight in grams

5. DETERMINATION OF PORE WATER

$t_2 = T - t_1$
t_1 = % shrinkage water
t_2 = % pore water
T = % water of plasticity

6. DETERMINATION % VOLUME SHRINKAGE

$$b = \frac{Vp-Vd}{Vd} \times 100$$

b = % volume shrinkage
Vp = plastic volume
Vd = dry volume

7. DETERMINATION OF LINEAR SHRINKAGE

$$a = 100\left(\sqrt[3]{1+\frac{b}{100}} - 1\right)$$

a = % linear shrinkage

FORMULAS FOR CALCULATING PHYSICAL PROPERTIES OF CERAMIC MATERIALS

8. DETERMINATION OF THE TRUE SPECIFIC GRAVITY

$$Gt = \frac{w-p}{(w-p)-(w_2-w_1)}$$

Gt = true specific gravity
w = weight of stoppered pycnometer and sample
p = weight of stoppered pycnometer
w_1 = weight of stoppered pycnometer filled with water
w_2 = weight of stoppered pycnometer sample and water

9. DETERMINATION OF APPARENT POROSITY

$$P = \frac{Sf-Wf}{Vf} \times 100$$

P = % apparent porosity
Sf = weight of saturated fired test piece in grams
Wf = weight of fired test piece in grams
Vf = volume of fired test piece in cc.

10. DETERMINATION OF VOLUME CHANGE

$$b_l = \frac{Vd-Vf}{Vd} \times 100$$

b_l = % volume change
Vd = volume of the dry test piece in cc.

11. DETERMINATION OF APPARENT SPECIFIC GRAVITY

$$G = \frac{Wf}{Vf-(Sf-Wf)}$$

G = apparent specific gravity

12. DETERMINATION OF BULK SPECIFIC GRAVITY

$$Gb = \frac{Wf}{Vf}$$

Gb = bulk specific gravity

13. DETERMINATION OF MODULUS OF RUPTURE

$$M = \frac{3PL}{2bd^2}$$

M = modulus of rupture in kg./sq. cm.
P = breaking load in kg. (read to nearest 0.1 kg.)
L = distance between knife edges in cm.
b = breadth of bar in cm.
d = depth of bar in cm.

14. DETERMINATION OF TRANSVERSE STRENGTH

$$M = \frac{8PL}{\pi d^3}$$

M = modulus of rupture
P = load in pounds at rupture
L = distance between supports
d = diameter of specimen in inches
π = 3.1416

FORMULAS FOR CALCULATING PHYSICAL PROPERTIES OF CERAMIC MATERIALS

SHRINKAGE CONVERSION TABLES

For a complete explanation of the following tables, the reader is referred to the original paper by WESTMAN, Jour. Am. Ceramic Soc. 11, No. 9, p. 715, (1928).
Copyright by A. E. R. Westman, reprinted by permission.

Relations Between Linear and Volume Change

Nature of change	Percentage basis	Equations* for converting Volume change to linear change	Equations* for converting Linear change to volume change	Percentage basis	Nature of change
Expansion	Initial values	$a=100\left[\sqrt[3]{\frac{b}{100}+1}-1\right]$	$b=100\left[\left(\frac{a}{100}+1\right)^3-1\right]$	Final values	Contraction (or shrinkage)
	Final values	$a=100\left[\sqrt[3]{\frac{b}{100}-1}+1\right]$	$b=100\left[\left(\frac{a}{100}-1\right)^3+1\right]$	Initial values	

Conversion of Percentage Basis

Nature of change in size	Equations* for converting Percentage of initial value to final value	Percentage of final value to initial value
Expansion	$c=\frac{100d}{100+d}$	$d=\frac{100c}{100-c}$
Contraction	$c=\frac{100d}{100-d}$	$d=\frac{100c}{100+c}$

Calculation of Design Factors, Combination of Changes

Nature of changes	Percentage basis	Equation* for calculating resultant per cent change	Percentage basis	Nature of changes
Both expansions	Initial values	$Z=X+Y+\frac{XY}{100}$	Final values	Both contractions (or shrinkages)
	Final values	$Z=X+Y-\frac{XY}{100}$	Initial values	

*In the equations, a = % linear change, b = % volume change, c = % change based on final value, and d = % change based on initial value; substitutions are to be made arithmetically. Z = % resultant change or overall change, X = % change in first process (e.g. drying), and Y = % change in second process (e.g. firing); if X and Y are percentages of final values, Z will be a percentage of the final value.

SHRINKAGE CONVERSION TABLE
TABLE I

Four Figure Table for Converting:

(1) Volume Drying Shrinkage (per cent of plastic volume) to Linear Drying Shrinkage (per cent of plastic length),

(2) Volume Firing Shrinkage (per cent of unfired or dry volume) to Linear Firing Shrinkage (per cent of unfired or dry length), and

(3) Volume Expansion (per cent of final volume) to Linear Expansion (per cent of final length).

Per cent volume change	Per cent volume change: 0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	Differences

SHRINKAGE CONVERSION TABLE

TABLE III

Four Figure Table for Converting:

(1) Drying Shrinkage (per cent of plastic size) to Drying Shrinkage (per cent of dry size),

(2) Firing Shrinkage (per cent of unfired or dry size) to Firing Shrinkage (per cent of fired size), and

(3) Expansion (per cent of final size) to Expansion (per cent of initial size).

SIEVES AND SCREENS

The following terms are often employed in reporting the results of a screen analysis.

Cumulative Per Cent is the term employed to express the percentage of the total amount of a material which would remain on a testing sieve if only one sieve were used for testing the entire sample; to obtain the **cumulative weight,** it is necessary to add the weight of all of the material which remains on sieves coarser than the one in question to the amount remaining on the sieve in question. When such data is plotted as a curve, each point on the curve represents the *total* material that would be retained if only the one sieve represented by that particular point were used in the sieve analysis.

Effective Size is a term customarily employed in specifications for filtration sands; effective size is measured by that opening in millimeters which will just pass 10% of a representative sample of sand.

Uniformity Co-efficient is the numerical value obtained by dividing the sieve opening (in millimeters) which will pass 60% of the sample by the sieve opening (in millimeters) which will just pass 10% of the sample.

CERAMIC EQUIVALENT WEIGHTS

Based Upon the International Atomic Weights of 1933.
Compiled by F. C. SMITH, B. S. (Chem. Eng.) and R. O. HUMMEL
of The Harshaw Chemical Co., Cleveland, Ohio.

Abbreviations used in the table:

anhyd., anhydrous
atm., atmosphere of pressure
d., decomposition
diss., dissociation
$-H_2O$, loss of 1 mole water
monocl., monoclinic
m. p., melting point
$-O$, loss of 1 atom of oxygen
RO, base equivalent
R_2O_3, amphoteric equivalent
RO_2, acid equivalent
subl., sublimes
<, below or less than
>, above or greater than

Mineral or Compound	Formula	Formula Weight	Equivalent Weight			Melting Point °C.

FLOW MEASUREMENT

From Information Furnished by Members of the Technical Staff of
The Bailey Meter Co., Cleveland, Ohio

Nomenclature.—

C = Coefficient of Discharge; unit: a ratio.
W_h = Rate of flow; unit: pounds per hour.
ρ = Density of flowing fluid; unit: pounds per cubic foot.
ρ'_f = Density of dry air at 29.92 inches of mercury pressure and at the actual (experimental) temperature; unit: pounds per cubic foot.
ρ'_a = Density of saturated steam vapor at 60°F.; unit: pounds per cubic foot.
G_f = Specific gravity of air or gas under actual (experimental) conditions referred to air at 29.92 inches of mercury pressure and 60°F. as unity; unit: a ratio.
H = Differential head; unit: inches of water.
H_1 = Differential head; unit: inches of mercury.
h = Differential head; unit: inches of flowing fluid.
d_1 = Diameter of pipe; unit: inches.
d_2 = Diameter of orifice; unit: inches.
S = Saturation of air or gas mixture with moisture in per cent divided by 100, under actual (experimental) conditions.
p'_f = Pressure of saturated steam at actual (experimental) temperature; unit: inches of mercury.
p_f = Observed absolute pressure (equal to barometric reading plus gage reading in inches of mercury); unit: inches of mercury.

One of the most convenient methods for measuring the flow of fluids through a conduit, is by means of a head meter. In the head meter, a primary element is placed in the flowing fluid to produce a pressure difference or *differential head* which the secondary element then uses as an indication of the rate of flow. The primary element produces the differential head either by constricting the flow (orifice, venturi tube, flow nozzle, weir, etc.) or by measuring the impact of the flowing fluid (pitot tube). The secondary element consists of some form of manometer for measuring the differential head produced by the primary element.

If the flow is to be measured accurately, the flowing fluid must be free from turbulence, such as would be produced by obstructions and bends in the piping too near the orifice location, and must not be a pulsating flow as would be produced by reciprocating engines, pumps, and certain types of blowers. The flowing fluid must also be non-viscous unless corrections are applied, corrections which are beyond the scope of this short presentation. In general, at least, a length equal to 20 diameters of straight pipe without valves or fittings should precede the primary element location.

Manometers.—Manometers usually consist of two glass tubes connected at the bottom. The differential pressures are connected to the tops of the glass tubes. The glass tubes are usually filled half full with a liquid and the difference between the levels will give the *differential*. Liquids commonly used in manometers are: water (sp. gr. 1.00); carbon tetrachloride (sp. gr. 1.60); acetylene tetrabromide (sp. gr. 2.96); and mercury (sp. gr. 13.56). Since differentials are usually expressed in inches of water, it is necessary to convert measurements with other liquids to the corresponding head of water. This is done by multiplying the differential head of the liquid by its specific gravity. If the liquid in the gauge is under a column of the liquid whose flow is being measured, the specific gravity of the flowing liquid must be subtracted from the specific gravity of the gage liquid. If, for example, the flow of water (sp. gr. = 1) is being measured by a mercury manometer (sp. gr. = 13.56), then

$$H_1(13.56-1) = H$$

The weight of gases can usually be neglected except at high pressures.

Orifices.—One of the simplest of

the primary elements used to produce a throttling action is the *orifice plate*. It consists of a thin disc of stainless steel or monel metal in the center of which is a hole smaller in diameter than the inside of the pipe with which it is to be used. The maximum reduction in pressure produced by this throttling action is at a point, downstream from the orifice plate, called the *vena contracta*. The position of the vena contracta with a given orifice is practically the same for all rates of flow. Since the pressure is partially restored after passing the vena contracta, it is desirable to make the downstream connection to the manometer as near the vena contracta as possible.

The outside diameter of the orifice plate should fit snugly inside the bolt circle of the pipe flange so that the orifice hole will be concentric with respect to the pipe diameter. For use in pipes of six inches or less in diameter, the orifice plate should be $\frac{1}{16}$ inch in thickness; for pipe diameters from 6 inches up to 15 inches the orifice plate should be at least $\frac{1}{8}$ inch in thickness. It is essential that the inside of the orifice hole be smooth and free from burrs. The upstream edge must be sharp and square, and the downstream side should have a 45° bevel to $\frac{1}{32}$ inch edge thickness.

The connections to the orifice should be made by means of $\frac{1}{2}$ inch pipe nipples. These nipples should be filed flush with the inside of the pipe and must, under no conditions, project into the flowing stream. The upstream connection should be made about one pipe diameter from the orifice plate. The downstream connection should be at the vena contracta. If an easily condensed gas or vapor (e. g., steam) is being measured, a reservoir for collecting condensate (water) must be placed on each nipple. Each reservoir should hold about 20 or 30 cubic inches of condensed liquid, and these reservoirs must be so mounted that the liquid level is exactly at the same height in both, otherwise a false differential will be created.

Selection and Calculation of the Proper Size of Orifice.—The general formula for calculating orifices is:

$$W_h = 360 \times (d_2)^2 \times C \sqrt{\frac{H\rho}{1-\left(\frac{d_2}{d_1}\right)^4}}$$

These formulas do not take into account the compressibility of the gas nor the thermal expansion of the orifice plate but are sufficiently accurate for most practical applications. Since W_h, d_2, and H are variables, it is necessary to assign values to two of these factors in order to solve the equation. The diameter of the orifice hole d_2 is usually selected so as to give the maximum H when the flow W_h is at the maximum. H is, therefore, selected before starting the design of the orifice. It is desirable to make H as large as practical for more accurate reading if the differential is to be read by means of a U-tube manometer. If a flow meter is to be used, the H will usually be the maximum head for which the flow meter is designed. H is also limited in some instances by the pressure loss that can be tolerated, as is the case when measuring flows under low pressures. The pressure loss due to the orifice may be calculated from curve No. 3 on per cent differential head lost.

The most practical method for calculating an orifice is by trial since it eliminates solving a fourth degree equation. A value for d_2 is arbitrarily chosen, then from the orifice ratio d_2/d_1, a value for C is found from curves No. 2 on discharge coefficients. These values are then placed in the equation and the equation is solved for W_h. If an approximate value for the maximum flow through the pipe line is known, the value for d_2 is altered until the desired value for W_h is secured.

When the orifice is in operation, of course, the values for d_1, d_2, C, and ρ are constant so long as the state of the fluid does not differ from that for which the orifice was designed. These factors are then multiplied together to give a new constant by which the instantaneous value for H as read from the manometer or meter may be multiplied to give the rate of flow per hour at that instant. This is done by writing equation No. 1 (see below) in this form:

FLOW MEASUREMENT

$$W_h = \left[(360) \times (d_2)^2 \times (C) \times \sqrt{\frac{1}{1-\left(\frac{d_2}{d_1}\right)^4}} \times \sqrt{\rho} \right] \times \sqrt{H}$$

The terms enclosed within the brackets being the constant for the orifice.

The desirability for designing an orifice to give the maximum differential head will be appreciated when it is realized that the differential head developed by a flow through an orifice is a square root relationship, so that if an orifice, for example, has twice the necessary capacity, it will develop only one-fourth the head otherwise obtainable. If no estimate of the maximum flow is available, it may be necessary to design and build a trial orifice and from trial tests run with this orifice sufficient data can be secured from which an orifice of correct proportions can be designed.

Example.—The flow of water through a 6 inch pipe is estimated to be 180,000 pounds per hour. What should be the diameter of the orifice hole if used with a 10 inch manometer? Where should the downstream tap be located? What is the pressure loss due to the orifice at maximum flow? What is the flow through the 6 inch pipe when an orifice, designed for the conditions mentioned above, produces a 5 inch differential on the mercury manometer? The water (sp. gr. = 1) to be measured is at a temperature of 60°F., and therefore $\rho = 62.4$; the manometer to be used has a maximum range of 10 inches of mercury (sp. gr. 13.56), or $H = 10(13.56 - 1) = 125.6$ inches of water.

For a trial a 3 inch orifice hole may be assumed. The ratio, d_2/d_1, will then be 3.00/6.00 = 0.50. From curve No. 2 it will be found that for a 0.50 ratio and a 6 inch pipe, C is 0.608. These values are then substituted in equation No. 1, and grouping the values which are constants gives the following:

$$W_h = (360) \times (3)^2 \times (0.608) \sqrt{\frac{1}{1-\left(\frac{3.00}{6.00}\right)^4}} \times \sqrt{62.4} \times \sqrt{125.6}$$

$$= 16{,}100 \times \sqrt{125.6}$$

$$= 180{,}100 \text{ pounds per hour.}$$

From curve No. 1 it will be found that for a 0.50 ratio, the downstream connection should be 0.6 diameters from the orifice plate to bring its position at the middle of the vena contracta; *i. e.*, $0.6 \times 6 = 3.6$ inches, and the minimum distance allowable is $0.4 \times 6 = 2.4$ inches, and the maximum distance allowable is $0.75 \times 6 = 4.5$ inches.

The pressure loss due to the orifice is calculated by multiplying H by a constant as read from curve No. 3. Thus, in the example given above, the pressure lost with a 0.50 ratio is 0.72 of the head which at the maximum flow is: $(0.72) \times (125.6) = 90.5$ inches of water, or since (inches of water) $\div 27.72$ = pounds per square inch, the pressure loss due to the orifice when 180,000 pounds per hour is flowing through the pipe will be: $90.5 \div 27.72 = 3.26$ pounds per square inch.

The rate of flow for 5 inches of mercury differential is calculated as follows:

$$H = 5 \times (13.56 - 1) = 62.8 \text{ inches of water}$$

$$W_h = 16{,}100 \times \sqrt{62.8}$$

$$= 127{,}400 \text{ pounds per hour.}$$

ORIFICE FORMULAS

For liquids:

(1) $W_h = (360) \times (d_2)^2 \times (C) \times \sqrt{\frac{(\rho) \times (H)}{1-\left(\frac{d_2}{d_1}\right)^4}}$

For dry gases under actual (experimental) conditions of temperature and pressure:

(2) $W_h = (360) \times (d_2)^2 \times (C) \times \sqrt{\frac{(\rho_f)\ (G_f)\ (}{1-\left(\frac{d_2}{d_1}\right)^4}}$

For wet gases under actual (experimental) conditions of temperature and pressure:

(3) $W_h = (360) \times (d_2)^2 \times (C) \times \sqrt{\frac{[\rho'_f \times G_f (p_f - p'_f) + (\rho'_a)\ \overline{(S)}]\ H}{1-\left(\frac{d_2}{d_1}\right)^4}}$

PITOT TUBE FORMULAS

Two common types of pitot tubes are the *combined impact reverse*, and the *combined impact static*. In the combined impact reverse one opening faces upstream and the other opening downstream. In the combined impact

ELECTROMETRIC DETERMINATION OF pH

The "pH" values of aqueous solutions are expressed on a scale that is to a large extent an arbitrary one. Sorensen originally considered pH to be equal to $-log\ C_{H+}$, where C_{H+} is the hydrogen ion concentration of the solution. This relation is now considered to be only an approximation. Moreover, pH is not equal to $-log\ a_{H+}$, where a_{H+} is the thermodynamic "activity" of hydrogen ions in the solutions, for the latter can never be exactly determined. The uncertainty of the magnitude and constancy of the liquid-junction potential deprives the pH of much of its fundamental significance. See D. I. Hitchcock and A. C. Taylor, *J. Am. Chem. Soc.*, **59**, 1812 (1937); **60**, 2710 (1938); D. A. MacInnes, D. Belcher, and T. Shedlovsky, *ibid.*, **60**, 1094 (1938); M. Dole, "The Glass Electrode," John Wiley and Sons, Inc., New York, 1941, pp. 280–304; R. G. Bates, *Chem. Rev.*, **42**, 1 (1948).

The pH of an aqueous solution is defined operationally by the following equation:

$$pH = pH_S + \frac{(E - E_S)}{0.000198404T} \qquad (1)$$

in which pH_S is the pH assigned to the standard buffer solution with which the pH cell is standardized, E and E_S are the electromotive forces of a suitable pH cell with unknown and standard, respectively, T is the temperature on the absolute (Kelvin) scale, and 0.000198404 is $2.30259R/F$, where R is the gas constant and F is the faraday. The values of $0.000198404T$ from 0° to 70°C are given in Table I.

Table I

Values of $0.000198404\ T$ at Various Temperatures

t°C	Value	t°C	Value	t°C	Value	t°C	Value
0	0.054196	18	0.057767	25	0.059156	38	0.061735
5	0.055188	19	0.057966	26	0.059355	40	0.062132
10	0.056180	20	0.058164	27	0.059553	50	0.064116
14	0.056974	21	0.058363	28	0.059751	60	0.066100
15	0.057172	22	0.058561	29	0.059950	70	0.068084
16	0.057371	23	0.058759	30	0.060148		
17	0.057569	24	0.058958	35	0.061140		

In most modern pH meters, the pH can be read directly when the instrument is adjusted to the proper value of the temperature and is "standardized" or made to read correctly at the pH of the standard. These instruments most commonly utilize a cell with glass and saturated calomel electrodes. In order to check adequately the proper operation of the meter, two standards differing in pH by at least two units should be used.

pH Standards

The pH_S values of five solutions suitable for the standardization of pH cells are given in Table II. These values have been made to correspond as closely as possible to the relationship:

$$pH_S = -\log C_{H+} f_{H+} \qquad (2)$$

where f_{H+} is a "conventional" or defined activity coefficient for hydrogen ion, numerically equivalent to the mean activity coefficient of an average uni-univalent electrolyte in the same solution. See "Standardization of pH Measurements Made with the Glass Electrode," National Bureau of Standards *Letter Circular LC993*,

Washington, D. C.; R. G. Bates, *Analyst*, **77**, 653 (1952). Directions for the preparation of these five standards are given in Table III.

Disodium hydrogen phosphate is the only one of the buffer salts that is appreciably hygroscopic. The tartrate, phthalate, and phosphates can be dried at 110°C before use. Potassium tetroxalate dihydrate should not be dried at temperatures above 60°C, nor should borax be heated above normal room temperatures. Standard samples

Table III

Directions for Preparing Standard Buffer Solutions

Standard	Preparation
K-tetroxalate, 0.05 *M*	Dissolve 12.71 g $KH_3(C_2O_4)_2 \cdot 2H_2O$ in water and dilute to 1 liter.
KH-tartrate, satd. at 25°C	Shake an excess of the salt for several minutes with water the temperature of which is 25 ± 3°C. Decant or filter to remove suspended material.
KH-phthalate, 0.05 *M*	Dissolve 10.21 g of potassium acid *o*-phthalate, $KHC_8H_4O_4$, in water and dilute to 1 liter.
KH_2PO_4, 0.025 *M*; Na_2HPO_4, 0.025 *M*	Dissolve 3.40 g KH_2PO_4 and 3.55 g anhydrous Na_2HPO_4 in water and dilute to 1 liter.
Borax, 0.01 *M*	Dissolve 3.81 g $Na_2B_4O_7 \cdot 10H_2O$ in water and dilute to 1 liter. The water should be freed of carbon dioxide by boiling or purging with CO_2-free air.

of the salts can be purchased from the National Bureau of Standards. The tetroxalate, phthalate, phosphate, and borax solutions can be stored in bottles of resistant glass or polyethylene and should be replaced every two months. The tartrate solution is subject to molding and must be replaced after a few days unless a preservative (*e.g.*, a small crystal of thymol) is added.

Interpretation of pH Measurements

The measured pH is to be regarded as a reproducible number indicating in a semi-quantitative way the "acidity" or "alkalinity" of the medium. If the medium is a dilute aqueous solution of simple ionic and molecular species, the measured pH approaches $-\log C_{H^+}f_{H^+}$, where f_{H^+} is the activity coefficient of hydrogen ion on the conventional scale chosen to establish the standards.

pH Cells

In the operational definition above, E and E_S are the emf values of a cell such as:

$$\text{-Hydrogen ion electrode; Solution} \mid \text{KCl (Satd.), } Hg_2Cl_2 \text{ (s), } Hg^+ \qquad (A)$$

where the vertical line indicates a liquid-liquid junction. This pH cell consists of (*a*) an electrode the potential of which depends upon the hydrogen ion activity of the solution and (*b*) a reference electrode the potential of which is independent of the composition of the solution at any given temperature. Calomel electrodes of the 0.1 *N*, 1 *N*, or saturated types are most widely used as the reference, and the bridge between the reference and the solution of unknown pH is almost always either a 3.5 *M* or saturated solution of potassium chloride. In theory, the hydrogen gas electrode is the only perfect hydrogen ion electrode, and corrections must be applied to E and E_S for the imperfect response of other electrodes under certain conditions. In practice, the glass electrode is used more widely than other hydrogen ion electrodes. The quinhydrone and antimony electrodes display a satisfactory hydrogen ion response over a part of the pH scale.

Notes on the Hydrogen Electrode

Directions for preparing the hydrogen electrode may be found in W. M. Clark, "The Determination of Hydrogen Ions," 3rd edition, 1928, Williams and Wilkins Co., Baltimore, Md.

The potentials of hydrogen electrodes vary with the partial pressure of hydrogen gas in equilibrium with the platinum surface, which is in turn dependent on the barometric pressure and the vapor pressure of water. The observed electromotive forces of cells with hydrogen electrodes are customarily corrected to a partial pressure of hydrogen of 760 mm. The barometric corrections, E_b, in volts to be added to the observed reading, are listed in Table IV. They were calculated by the equation:

$$E_b = \frac{0.000198404T}{2} \log \frac{760}{x} \qquad (3)$$

where x is the corrected barometric reading minus the vapor pressure of water at the absolute temperature T.

The hydrogen electrode cannot be used in the presence of salts of heavy metals nor easily reduced substances in general. Thus, unsaturated organic acids, some alkaloids, etc., are reduced by hydrogen in the presence of the finely divided noble metal electrode, which acts as a catalyst for the reduction. For this reason, an electrode coated with palladium should be used in phthalate solutions. The electrode is very sensitive to traces of oxygen, so that highly purified hydrogen must be used. The

ELECTROMETRIC DETERMINATION OF pH

Table IV

Barometric Corrections, E_b, for the Hydrogen Electrode

Corrected barometer reading in mm.	E_b in Volts at t°C.

735	+.0005	+.0006	+.0006	+.0007	+.0009	+.0010	+.0012	+.0015

commercial compressed hydrogen, however, is generally sufficiently pure for practical work.

Example

The electromotive force, E, of a H_2,satd. calomel cell at 25°C was found to be 0.5227 volt, with the hydrogen electrode immersed in a buffer solution which was 0.01 M with respect to both acetic acid and sodium acetate. The corrected barometric reading was 740 mm. The electromotive force, E_S, with the standard phosphate solution ($pH_S = 6.86$) in the cell was 0.6499 volt for a corrected barometric reading of 750 mm. What is the pH of the first solution?

From Table IV, the barometric correction to the first measurement is +0.0008 volt and to the second +0.0006 volt; hence, E and E_S are 0.5235 and 0.6505, respectively. From Table I $0.000198404T$ is found to be 0.05916 at 25°C. The pH is calculated by Equation 1:

$$pH = 6.86 + \frac{0.5235 - 0.6505}{0.05916} = 4.71$$

Measurement of pH with the Quinhydrone Electrode

The quinhydrone electrode is formed by dipping a bright platinum or gold electrode into a solution saturated with quinhydrone, an equimolecular mixture of benzoquinone and hydroquinone. The quinhydrone electrode is negative with respect to the saturated calomel reference (as indicated in cell A) only above pH 7.7; hence, E in Equation 1 must be given a positive sign above 7.7 and a negative sign below.

Examples

The emf (E_S) of a quinhydrone-saturated calomel cell containing the standard 0.05 M phthalate buffer solution is −0.2235 volt at 20°C where $pH_S = 4.00$. The minus sign indicates that the quinhydrone electrode is the positive electrode of cell A. When two "unknown" solutions were placed consecutively in the cell, the emf was

found to be 0.1009 volt (quinhydrone positive) and 0.0466 volt (quinhydrone negative) at the same temperature. What are the pH values of these solutions?

The two values of E are -0.1009 and $+0.0466$, respectively. From Equation 1 and Table I:

$$pH = 4.00 + \frac{(-0.1009) - (-0.2235)}{0.05816} = 6.11$$

and

$$pH = 4.00 + \frac{0.0466 - (-0.2235)}{0.05816} = 8.64$$

Notes on the Quinhydrone Electrode

An electrode having an area of at least one square centimeter is desirable. Platinum electrodes should be clean and free from stains, but need not be highly polished. Methods of cleaning platinum electrodes include (*1*) heating in fresh cleaning solution (sulfuric acid and potassium dichromate mixture), washing well with water and drying in air for twenty minutes; (2) boiling in nitric acid, then in 5 to 10% sodium acid sulfite, rinsing well with water and using at once.

Commercial quinhydrone is usually satisfactory, and an excess of the solid may be added directly to the solution. If the quinhydrone has been heated or exposed to the light, some decomposition with loss of quinone may have taken place, and the compound should be recrystallized from water at 70°C and dried at room temperature in subdued light.

The quinhydrone electrode cannot be used in the presence of active reducing or oxidizing agents, and it is also subject to protein and salt errors. Above pH 8.5 it becomes unreliable, both because hydroquinone has acid properties (K'_a is approximately 10^{-10}) and because it is appreciably oxidized by air in alkaline solutions.

Notes on the Antimony Electrode

The potential of a piece of metallic antimony, the surface of which is lightly coated with antimony oxide, is a function of the pH of the solution in which the metal is immersed. If the metal is cast in air, sufficient oxide is formed on the surface to make further addition to the solution unnecessary. Inasmuch as water takes part in the electrode reaction, the activity of water in the solution must be constant. The electrode is rugged and of low resistance; hence, the problem of electrical leakage and pickup is minimized. Reproducible pH measurements may be made in ordinary solutions to ± 0.15 pH over the range of pH 3 to 11.

Impurities in the metal lower the stability of the electrode, especially in the acid range. Traces of copper in acid solution cause large deviations, and for reliable results the copper content should be less than 0.1 part per million. The presence of metals more noble than antimony causes a similar behavior. Dissolved oxygen contributes to stability of the electrode in acid solutions but causes a deviation from the theoretical emf-pH curve in alkaline solutions. Agitation of the solution has some effect upon the potentials obtained. Too low pH values are obtained in solutions of hydrogen peroxide, potassium permanganate, sodium chromate, and other oxidizing agents.

Measurement of pH with the Glass Electrode

A typical cell for pH measurements with a glass electrode is:

$$\underset{a}{\text{Ag, AgCl(s), 0.1 } N \text{ HCl}} \;\|\; \underset{b}{\text{glass}} \;\|\; \underset{c}{\text{test sample}} \;|\; \underset{d}{\text{satd.KCl,}} \; \underset{e}{\text{Hg}_2\text{Cl}_2\text{(s), Hg}} \qquad (B)$$

The emf of the cell is the sum of the potentials developed at a, b, c, d, and e, plus a small "asymmetry potential" in the glass membrane. If the 0.1 N HCl in contact

with the silver-silver chloride electrode is not changed, potentials *a* and *b* will remain constant. Potential *e* is constant also, and the liquid junction potential, *d*, is small and nearly constant if the liquid junction is made properly. Therefore, *E* is a function of the potential *c* between the glass and the test sample providing there is no change in the asymmetry potential of the glass electrode. The calculation of pH is made by Equation 1.

Notes on the Glass Electrode

Glass electrodes are characterized by high electrical resistance (20 to 1,000 megohms), a large change of resistance with temperature, a changing asymmetry potential with chemical attack of the glass membrane, and a departure (error of the glass electrode) from the theoretical hydrogen electrode response at both ends of the pH scale. In practice, glass electrodes are found to be of satisfactory sensitivity, to reach equilibrium rapidly, and to maintain constant potentials for considerable lengths of time. The potential of a glass electrode is not affected by the presence of oxidizing or reducing agents. For complete information concerning the glass electrode and its applications, see M. Dole, *loc. cit.*

Errors of the Glass Electrode—The departure of the glass electrode at very low pH values appears to result from a lowered activity of water in the solution. This error causes the apparent pH value to be too high. Alkali metal ions in solutions of pH greater than 9 may induce appreciable errors that become much greater at elevated temperatures. These cause the measured pH to be too low. The magnitude of the departure is a function of the composition of the glass, and commercial glass electrodes of low sodium error are now available. Tables of corrections permit accurate pH values to be obtained with these glass electrodes at very high alkalinities.

Calomel Reference Electrodes

The standard potential, $E^{o\prime} + E_j$, of the calomel reference electrode is the emf of the cell:

$$\text{Pt; } H_2(g), H^+ \text{ (unit activity) } | \text{ Satd.KCl, calomel electrode} \qquad (C)$$

including the liquid junction potential (E_j) at the boundary represented by the vertical line. The standard potentials of the 0.1 *N* and saturated calomel electrodes are given in Table V.

Table V

Values of the Standard Potential of Calomel Electrodes at 12°, 25°, and 38°C (Uncertainty: ±0.0005 volt)

Electrode	$E^{o\prime} + E_j$ in volts at 12°C	25°C	38°C
0.1 *N* Calomel: Satd. KCl, 0.1 *N* KCl, $Hg_2Cl_2(s)$, Hg	0.3362	0.3356	0.3352
Satd. calomel: Satd. KCl, $Hg_2Cl_2(s)$, Hg	0.2528	0.2444	0.2375

COLORIMETRIC DETERMINATION OF HYDROGEN ION CONCENTRATION

The colorimetric determination of *pH* is based upon the principle that if an indicator be added to different solutions and it assumes the same transition shade, then such solutions are supposed to have the same *pH*. However, the characteristics of indicators vary with different solvents; e.g., in mixtures of water and alcohol. It should be emphasized that the *pH* range of the indicators as given in tables which follow this section hold for aqueous solutions. Therefore, in the measurement of *pH* in tinctures, a correction should be applied for the effect of the medium.

To the solutions, the *pH* of which are to be determined, measured volumes of suitable indicators are added and the color compared with that of the same indicator in solutions of known *pH*. The method, therefore, is a comparison procedure the accuracy of which depends primarily upon the correctness of the standard reference solutions. The *pH* of the latter is determined by means of the hydrogen electrode. The standardization according to the potentiometric method is, therefore, the primary procedure upon which the procedure rests. Such standard reference solutions are called "*buffer mixtures.*" Buffer mixtures of various compositions have been described in the literature (compare Clark, *The Determination of Hydrogen Ions*, Baltimore, Md., 1928; Kolthoff, *Indicators*, translated by Furman); the most popular set of buffers is that of Clark and Lubs which follows.

Preparation of Buffer Solutions.—Purity of Materials.

Hydrochloric acid, 0.2 *N* and 0.1 *N*, ordinary C. P. grade prepared and standardized according to the usual titrimetric procedure. (Cf. Section on *Titrimetric Solutions.*)

Sodium hydroxide, 0.1 *N*, prepared carbonate free and standardized according to the usual titrimetric procedure.

Potassium acid phthalate, $KHC_8H_4O_4$, M = 204.2. The C. P. product commercially available is of sufficient purity. It can be recrystallized from water and dried at 110–120°C. The purity of the material must be checked by a titration with standardized sodium hydroxide using phenolphthalein or thymol blue as an indicator. A 0.1 molar solution of the salt is prepared as a stock solution.

Monopotassium phosphate, KH_2PO_4, M = 136.2. The C. P. salt commercially available is recrystallized twice from water and dried at 110–120°C. A 0.1 molar solution of the salt is prepared as a stock solution.

Potassium chloride, KCl, M = 74.6. The C. P. product is recrystallized twice from water and is dried at 120°.

Boric acid, H_3BO_3, M = 62.0. The C. P. product is recrystallized from water and dried in the air. A 0.1 molar solution of boric acid in 0.1 molar potassium chloride is prepared as a stock solution.

COMPOSITION AND pH OF MacILVAINE'S BUFFER MIXTURES

Stock solution A, 0.2 *M* disodium phosphate: Dissolve 145 g C. P. clear crystals in 2 liters CO_2-free water. Titrate 10 ml with 0.1 *N* HCl and a drop of methyl orange indicator to match the tint shown by 30 ml of a solution containing 2.28 g C. P. KH_2PO_4 and 1.00 g C. P. NaCl in 250 ml H_2O. Adjust solution *A* to require 20.00 ml 0.1 *N* HCl in a repeating titration.

Stock solution B, 0.1 *M* citric acid: Dissolve 45 g C. P. clear crystals and dilute to 2 liters. Titrate 10 ml with 0.1 *N* NaOH (carbonate-free) and phenolphthalein indicator, and adjust solution *B* to require 30.00 ml in a repeating titration. To preserve solutions *A* and *B*, about 0.1% of toluene may be added.

To prepare the buffer mixtures, measure into a test tube the required volume of solution *A* for the desired *pH*, as shown in the table following, and add sufficient solution *B* to make the total volume exactly 10.00 ml. Cf. T. C. MacIlvaine, *J. Biol. Chem.*, **49**, 183 (1921); C. J. Schollenberger, *The Chemist-Analyst*, **19**, No. 3, No. 8 (1930).

Preparation and Properties of Indicator Solutions.—As a rule, water can be used as a solvent for indicators, but methyl yellow and the phthaleins must be dissolved in 90% alcohol. The various sulfonphthaleins and methyl red must be neutralized with sodium hydroxide before they are soluble in water. The former behave as dibasic acids, the indicator properties being determined by the magnitude of the second ionization constant. For most purposes it is sufficient to neutralize the strong sulfonic group, except that in cases where the *pH* of practically unbuffered solutions have to be measured, then more attention must be paid to the proper preparation of the indicator solution. To prepare an indicator solution, 100 mg of the indicator are rubbed in an agate mortar with the amount of 0.02 *N* sodium hydroxide specified in the table below. After solution of the indicator has taken place, sufficient water is added to make the volume 100 ml (0.1%) or 200 ml (0.05%).

The sulfonphthaleins originally introduced by Clark and Lubs (1917) and later extended by others (especially Barnett Cohen), are all indicators with very sharp color changes from yellow to intense red, blue or purple. Bromphenol blue in its transition interval shows a so-called "*dichroism*," the color of the indicator depending upon its concentration and the depth of the layer observed. It appears blue in a thin layer of the solution, and purple when viewed through a greater depth. In the colorimetric determination of *pH* this dichroism is very objectionable. Often the solution under examination contains substances which affect the light absorption of the indicator (alcohol, alkaloids; in alcoholic medium the color change is from yellow to blue); moreover, the indicator cannot be used in turbid solutions. When a layer of the liquid is viewed only a small amount of light from the bottom of the cell reaches the eye. Most of the light enters the cell through the side, is reflected by the particles and thus produces the effect of a thin layer of liquid with the accompanying blue color. A comparison of the color with that of the indicator in a clear buffer solution is scarcely possible, for a thin layer of fluid would have to be taken. Fortunately, Harden and Drake (*Jour. Am. Chem. Soc.*, 51, 562 [1929]) found that tetrabromphenol-tetrabromsulfonphthalein is a good substitute for bromphenol blue since it shows the same color change without the objectional dichroism.

A useful concentration of the indicator in the solution is of the order of 0.05 to 0.1%. Ordinarily the addition of 1 to 2 drops of such an indicator solution to 10 ml of the liquid to be investigated will give satisfactory results.

Indicator	Molecular Weight	ml 0.02 *N* NaOH per 100 mg of Indicator
Thymol blue	466	10.8
Tetrabromphenol blue	986	5.0
Bromphenol blue	669	7.5
Bromcresol green	698	7.2
Methyl red	269	18.6
Chlorphenol red	423	11.8
Bromthymol blue	624	8.0
Phenol red	354	14.2
Cresol red	382	13.1

COLORIMETRIC DETERMINATION OF HYDROGEN ION

Measurement of pH.—If the approximate value of the *pH* of a solution is unknown, the order of its magnitude must first be approximated in order to select the correct indicator for a more accurate evaluation. As a rule, a few simple tests will supply this information. For example, if a solution remains colorless after the addition of a drop of phenolphthalein, it indicates that the *pH* of the solution is less than 8.0 (cf. table of *Acid-Base Indicators*); if now a second test is made with methyl orange or bromphenol blue and the solution assumes the alkaline color of the indicator, it means that the *pH* is greater than 4.5. Therefore, such a solution has a *pH* value between 4.5 and 8.0. A few more tests with methyl red (*pH* interval 4.4 to 6.2); bromthymol blue (*pH* interval 6.2 to 7.6) and phenol red (*pH* interval 6.4 to 8.0) would serve to show the approximate *pH* value and suggest which indicators should be used for the exact determination. Instead of testing small amounts of the liquid with indicator solutions, indicator papers (litmus, congo, phenolphthalein, thymol blue, etc., papers) as a rule may be used by application of the spot method.

When the approximate value of *pH* is known, 3, 5, or 10 ml (depending upon the amount of liquid available) are measured out by means of a graduated cylinder and transferred into a test tube of pyrex glass or any other resistant glass. Soft glass should not be used because of the possibility of an alkaline reaction of the glass; the tubes should all be of the same inner size with a diameter of 1.5 cm and a length of 15 cm. A measured amount of the indicator solution is added carefully from a pipette of 1 ml volume which is graduated in 0.01 ml. As a rule, 1 to 2 drops of 0.1% indicator solution to 10 ml liquid will be the proper amount. Then some buffer solutions (4 to 6 ml) the *pH* of which overlaps that of the unknown are taken and treated in exactly the same way. Especially if one-color indicators are used, it is extremely important to add to the unknown and to the buffer solutions exactly the same amount of indicator. The best way of judging the color is to observe, against a white back-ground, the light transmitted through the whole length of the tube. A suitable colorimeter may be used as well, although it is not necessary in routine work. Enough reference solutions must be taken so that the color of the unknown falls between two of the series and not beyond them. If buffer solutions are used with *pH* differences of 0.2 respectively, the *pH* of the unknown can be approximated very easily to within 0.1, and with some practice to 0.05. With buffer solutions that differ by 0.1 *pH* unit or less, the *experimental* error can be reduced to 0.01 to 0.02 in *pH*.

ACID-BASE INDICATORS

An acid-base indicator is a weak acid or a weak base, the undissociated form of which has another color and constitution than the iogenic form. An indicator does not change its color from the purely acid to the purely alkaline side at a definite hydrogen concentration, but the color change takes place over a certain range of hydrogen ion concentrations. This range is called the color change interval and is expressed in the term of *pH* (the negative logarithm of the hydrogen ion concentration). A great number of substances show indicator properties although relatively few of them are practically applied for neutralization reactions and *pH* determinations. In general, weak acids should be titrated in the presence of indicators which change in slightly alkaline solutions. Weak bases should be titrated in the presence of indicators which change in slightly acid solutions.

Below are listed a number of indicators covering the range of *pH* 1.2 to *pH* 13.4. The letters *A* or *B* following the name of the indicator signify, respectively, that the compound is an indicator *acid* or *base*. Names set in bold face type are for those compounds which are especially recommended as indicators because they have proved to be satisfactory for practical use. Methods for the preparation of solutions of indicators will be found in the section *LABORATORY SOLUTIONS*.

The information given in the following table is from the two-volume work *VOLUMETRIC ANALYSIS* by Kolthoff and Stenger, published by Interscience Publishers, Inc., New York, 1942 and 1947, and reproduced with their permission.

† Sodium salt. * For the acid range. # For the alkaline range.

Indicator	*pH* Range	Quantity of Indicator per 10 ml	Color	
			Acid	Alkaline
Thymol blue (A) *†	1.2-2 8	1-2 drops 0.1% soln. in aq.	red	yellow
Pentamethoxy red (B)	1.2-2.3	1 drop 0.1% soln. in 70% alc.	red-violet	colorless

SELECTED LIST OF OXIDATION-REDUCTION INDICATORS

In the column headed π_0 are given the potentials, referred to the normal hydrogen electrode, at which the indicators are "half-changed"; these potentials are those of solutions one normal in hydrogen ions.

The information given in this table is from the two-volume work VOLUMETRIC ANALYSIS by Kolthoff and Stenger, published by Interscience Publishers, Inc., New York, 1942 and 1947, and reproduced with their permission.

* Distinct color change 1.20. † Color change 1.31.

Indicator	π_0 at $pH = 0$	Color Change	
		(Ox)	(Red)
Safranine T	0.24	red	colorless
Neutral red	0.24	red	colorless
Indigo monosulfonate	0.26	blue	colorless
Phenosafranine	0.28	red	colorless
Indigo tetrasulfonate	0.36	blue	colorless
Nile blue	0.41	blue	colorless
Methylene blue	0.53	green-blue	colorless
1-Naphthol-2-sulfonic acid indophenol	0.54	red	colorless
2,6-Dibromophenol indophenol	0.67	blue	colorless
Diphenylamine (diphenylbenzidine)	0.76 ± 0.1	violet	colorless
Diphenylamine sulfonic acid	0.85	red-violet	colorless
Erioglaucin A	1.0	red	green
Setoglaucin O	1.06	pale red	yellow-green
p-Nitrodiphenylamine	1.06	violet	colorless
o, *m*'-Diphenylamine dicarboxylic acid	1.12	blue-violet	colorless
o, *o*'-Diphenylamine dicarboxylic acid	1.26	blue-violet	colorless
o-Phenanthroline ferrous complex	1.14 *	pale blue	red
Nitro-*o*-phenanthroline ferrous complex	1.25 †	pale blue	violet-red

FLUORESCENT INDICATORS

Fluorescent indicators have the advantage over other indicators in that they may be used in titrating very turbid or strongly colored liquids.

Abbreviations: bl, blue; br, brown; dk, dark; g, green; lt, light; o, colorless; p, pink; st, strong; v, violet; wk, weak; y, yellow.

Name	*pH*	Color acid → base	Name	*pH*	Color acid → base
Benzoflavine	−0.3- 1.7	y → g	β-Methylesculetin	4.0- 6.2	o → bl

Quininic acid	4.0- 5.0	y → bl			

AN OUTLINE FOR QUALITATIVE ANALYSIS

By R. C. Hummell, Ph. D.

Preparation of Solution for Metal Analysis

A. If the sample to be analyzed is already in solution, acidify with nitric acid unless it is already acid.

B. If the sample is solid and metallic in appearance indicating a metal or alloy, dissolve in dilute nitric acid. (A few metals and alloys dissolve better in hydrochloric acid.) If a white residue remains from the treatment with nitric acid filter it off and dissolve it in boiling concentrated hydrochloric acid and test this solution for tin and antimony only.

C. If solid and non-metallic try to dissolve the sample first with water (cold and boiling), then if a residue is left, filter it and next try dilute nitric and hydrochloric acids successively, then concentrated hydrochloric acid, then aqua regia and if a residue still remains it must be filtered off and treated as an insoluble material.

D. Insoluble Material. (Cf. note following D2.) If a platinum crucible is available, mix the powdered "Insoluble" with about ten times its bulk of a mixture of equal parts of sodium carbonate and potassium carbonate and then fuse in the platinum crucible using a blast burner or Meeker burner. If a platinum crucible is not available an iron crucible may be substituted in which case a piece of sodium hydroxide about twice the size of a pea is substituted for the potassium carbonate. Heat the crucible and its contents for five minutes after a clear fusion is obtained. Then pour the melt on to a small piece of sheet-iron to solidify. Digest this with water until entirely disintegrated. Filter and treat the residue as directed in D1 and the filtrate as in D2.

D1. Dissolve the residue in dilute nitric acid and test for metals as outlined.

D2. Add the filtrate from digestion of the fusion above to the solution prepared especially for acid analysis as given in the tests for acid radicals.

Note. If the "insoluble" is white, before fusion its solubility in ammonium hydroxide or ammonium acetate should be tested as it might be silver chloride or lead sulfate and the ammonium hydroxide and ammonium acetate are solvents respectively for these.

All of the solutions prepared according to the directions given above, except D2 are to be analyzed for metals as directed in the following outline.

GROUP I

Add cold dilute hydrochloric acid drop by drop until precipitation is complete. Precipitate: $PbCl_2$, HgCl, AgCl. Filter. Wash with cold water. Save the filtrate to test for the subsequent groups.

Precipitate. Boil with 10 cc of water. Filter while hot.

Filtrate—$PbCl_2$. Add $K_2Cr_2O_7$ or K_2CrO_4 solution. Yellow ppt.—$PbCrO_4$ indicates Pb.	Precipitate—HgCl and AgCl Pour 5 cc NH_4OH over the precipitate.	
	Residue—If black indicates Hg.	Filtrate—Just acidify with HNO_3. White ppt. of AgCl indicates Ag.

GROUP II

To the filtrate from Group I add 1 cc of concentrated HNO_3 and evaporate just to dryness being careful near the end of the evaporation not to overheat any of the dry residue. Dissolve this residue with 2½ cc of concentrated HCl and 5 cc of water. Heat to boiling and pass H_2S into the solution for 5 minutes. Dilute to 40 cc and again pass in H_2S for 5 minutes. Filter 2 cc of this solution and dilute it to 5 cc and test with H_2S. If no precipitate forms then filter the main solution. If a precipitate does form, dilute the main solution to 100 cc and again pass in H_2S until precipitation is complete. Filter. Wash with hot water. Save the filtrate for subsequent groups.

AN OUTLINE FOR QUALITATIVE ANALYSIS

Precipitate: Sulfides of Hg, Pb, Bi, Cu, Cd, As, Sb, and Sn. To the precipitate add 15 cc of 2*N* NaOH, warm and stir. Filter. Wash with hot water.

Residue—Sulfides of Hg, Pb, Bi, Cu and Cd. Boil with 15 cc dilute HNO_3. Filter. Wash.

Residue—HgS. Dissolve in *aqua regia*. Boil out excess Cl_2. Add $SnCl_2$. A white or gray ppt. indicates Hg.

Filtrate—Make just alkaline with NaOH, then add 7 cc of 6*N* NaOH in excess. Warm and stir. Filter.

Filtrate—Na_2PbO_2. Acidify with acetic acid. Add K_2CrO_4. Yellow ppt. $PbCrO_4$. Indicates Pb.

Precipitate— Hydroxides of Bi, Cu, Cd. Dissolve in dilute HNO_3. Make strongly alkaline with NH_4OH. Filter.

Precipitate—$Bi(OH)_3$. Treat on filter with freshly prepared sodium stannite solution.* Immediate black coloration indicates Bi.

Filtrate— Ammoniated salts of Cu and Cd. If solution is deep blue Cu is present. If doubtful take a small portion and make acid with acetic acid, then add potassium ferrocyanide solution. Filter. A red ppt. on the white filter indicates Cu and is $Cu_2Fe(CN)_6$. If Cu is present add KCN to the main bulk of the filtrate until the solution is decolorized. Pass in H_2S. A yellow ppt. indicates Cd. If Cu is not present omit the addition of KCN.

Filtrate—Sodium thio-salts of As, Sb, Sn. Make just acid with acetic acid. Filter. Discard filtrate. **Precipitate**—Sulfides of As, Sb, Sn. Treat the well drained ppt. with 10 cc of hot conc. HCl. Stir thoroughly but do not boil. Dilute with 5 cc of water and filter.

Residue — Sulfides of As. Dissolve in NH_4OH adding a few drops of H_2O_2. Add magnesia mixture. A fine feathery ppt., slow in forming, indicates As and is $MgNH_4AsO_4$

Filtrate—Chlorides of Sb and Sn. Evaporate to a few cc. Place a few drops of this solution on a silver coin or platinum foil. Place a piece of tin so it touches the solution on the coin and the coin itself. A black coating on the coin indicates Sb. The main bulk of the solution is heated and some metallic iron added. After this reacts for a minute or so, decant off the clear solution and add to it $HgCl_2$. A white ppt. of $HgCl$ or a gray ppt. of Hg indicates Sn.

*Sodium stannite solution is prepared by adding sodium hydroxide solution to a few cc of stannous chloride solution until the white precipitate which is formed at first just dissolves.

GROUP III

Evaporate the filtrate from Group II to 10 cc. Test 1 cc for phosphates by adding to it 2 cc of conc. HNO_3 and 2 cc of ammonium molybdate reagent. Warm and allow to stand for at least 5 minutes. A fine yellow precipitate indicates phosphates. If phosphates are present remove them from the main solution as follows. First make the solution neutral with NH_4OH then add 3 cc of acetic acid and 5 cc of 50% ammonium acetate solution. Add to this sufficient $FeCl_3$ solution until no more precipitate forms and the solution becomes reddish in color. Dilute to 70 cc and boil until a condition is obtained where the precipitate on settling leaves the solution free from the reddish brown color. If necessary add more ammonium acetate to get this result. Filter.

Precipitate—Phosphates of Fe and possibly Al and Cr. Test for Al and Cr. Add 10 cc of dilute NaOH and 1 g Na_2O_2 to the ppt. Boil and then filter. Discard the ppt. Divide the filtrate into two parts.

Filtrate—Group III except possibly Fe, Al and Cr. Analyze according to procedure given for Group III with phosphates absent.

First portion—Make acid with HCl, then alkaline with NH_4OH. White flocculent ppt. indicates Al.

Second portion—Make acid with acetic acid, then add lead acetate. Yellow ppt. indicates Cr.

GROUP III
Phosphates Absent.

If phosphates are absent, or after removing them if present, add 1 g of NH_4Cl to the solution, then make it alkaline with NH_4OH and pass in H_2S to complete precipitation. Filter. Wash. Save filtrate for subsequent groups.

AN OUTLINE FOR QUALITATIVE ANALYSIS

Precipitate—Sulfides of Co, Ni, Mn, Zn, Fe and the hydroxides of Al and Cr. Digest cold with 25 cc of 1 N HCl. Filter. Wash.

Residue—CoS and NiS. Make a borax bead test on this residue. Blue bead indicates Co. Brown bead indicates Ni. Then dissolve residue in aqua regia and divide into two parts.

First portion—Add $NaHCO_3$ (solid) until effervescence ceases. Then add H_2O_2; development of deep green color indicates Co.

Second portion — Make alkaline with NH_4OH and add dimethylglyoxime. A red or scarlet ppt. indicates Ni.

Filtrate—Chlorides of Fe, Mn, Al, Cr and Zn. Evaporate to about 5 cc. add 5 cc of 30% NaOH solution and 3 cc of H_2O_2 and boil. Filter. Wash.

Precipitate — Hydroxides of Fe and Mn. Make a Na_2CO_3 bead test on this ppt. for Mn using a little $KClO_3$ in the bead in the last part of the fusion. Bluish-green bead indicates Mn. Dissolve the remainder of the ppt. in HCl and add NH_4CNS solution. Blood red color indicates Fe. If iron was added to remove phosphates a little of the original sample can be tested for Fe by boiling with HCl and testing with NH_4CNS.

Filtrate—$NaAlO_2$, $NaCrO_4$, Na_2ZnO_2. Make acid with HCl, then just alkaline with NH_4OH. Filter.

Precipitate — $Al(OH)_3$. This ppt. should be white and flocculent. If in doubt remove the paper from the funnel, roll it up, drop 2 drops of dil. HCl down the top, then 2 drops of dil. $Co(NO_3)_2$ soln. Coil a wire around the rolled paper and burn to an ash. Blue ash indicates Al.

Filtrate—Make acid with acetic acid. Add 2 cc ammonium acetate solution, then 2 cc of $BaCl_2$ solution. Filter.

Precipitate — Yellow ppt. indicates Cr. If white ppt. formed it is to be disregarded.

Filtrate—Pass H_2S. A white or gray ppt. composed of fine curdy particles indicates Zn. A milky suspension but not curdy is due to sulfur.

GROUP IV

Make the filtrate from Group III acid with acetic acid and evaporate to 10 cc. Filter if necessary and discard the precipitate. To the filtrate or clear solution add NH_4OH until alkaline, then add 15 cc of 95% ethyl alcohol and 15 cc of ammonium carbonate solution. Filter. Wash. Save the filtrate for subsequent group.

Precipitate—Carbonates of Ba, Ca, Sr and Mg. Dissolve in acetic acid. Add 5 cc of ammonium acetate solution and about 10 cc of potassium dichromate solution. Filter.

Precipitate—$BaCrO_4$. Moisten this ppt. with HCl and make a flame test with a platinum wire. Green flame indicates Ba.

Filtrate—Acetates of Sr, Ca, Mg and excess $K_2Cr_2O_7$. Make alkaline with NH_4OH and add 5 cc of alcohol. Filter.

Precipitate—$SrCrO_4$ and possibly some $CaCrO_4$. Boil with $(NH_4)_2CO_3$ and $(NH_4)_2C_2O_4$. Filter. Discard filtrate. Treat residue with acetic acid. Filter.

Residue—CaC_2O_4

Filtrate — Add Na_2SO_4 solution. White ppt. indicates Sr.

Filtrate—Ca and Mg salts. Add $(NH_4)_2C_2O_4$ solution. Filter.

Precipitate — CaC_2O_4 and possibly some MgC_2O_4. Treat with dil. H_2SO_4. Filter. To the solution add 5 cc of alcohol. Ppt. indicates Ca.

Filtrate — Add Na_2HPO_4 solution. White ppt. indicates Mg.

GROUP V

Evaporate the filtrate from Group IV to dryness. Heat the dry residue just short of a red heat until all of the ammonium salts have been expelled. Cool. Moisten with HCl and make a flame test with a platinum wire. An in-

tense yellow flame indicates Na. A pale violet flame indicates K. If flame is intense yellow view it through a small bottle containing a 10% solution of $KCr(SO_4)_2$ or several thicknesses of cobalt glass. A red flame as thus viewed indicates K. To test for NH_4^+—Take about 1 g of the original sample in a small beaker, add sodium hydroxide solution in excess, cover the beaker with a watch glass containing on the under side a moist piece of red litmus paper. Warm and observe the litmus paper. If it changes slowly and evenly from red to blue, NH_4^+ is present.

ACIDIC CONSTITUENTS

Detection of Groups of Acidic Constituents.

The following acid ions are provided for in this procedure: Chlorides, bromides, iodides, ferrocyanides, ferricyanides, thiocyanates, sulfates, sulfites, thiosulfates, chromates, fluorides, silicates, oxalates, tartrates, sulfides, carbonates, phosphates, borates, nitrates, nitrites, acetates, and permanganates.

Preliminary Examination. Detection of some acid radicals.—

1. Moisten with concentrated H_2SO_4 and observe results both cold and when heated.
   (a) Tartrates heated with H_2SO_4 turn brownish black and give odor of burnt sugar.
   (b) Carbonates give off colorless, odorless gas which will cloud a drop of lime water held over the reacting materials.
   (c) Some sulfides readily give off H_2S with H_2SO_4 and this can be detected by the odor or the darkening of a piece of paper moistened with $Pb(C_2H_3O_2)_2$.
   (d) Nitrites will give off brown fumes immediately.
   (e) Bromides will oxidize slowly with the formation of free bromine which can be recognized by the reddish brown color of the gas.
   (f) Iodides will liberate free iodine which is recognized by the purple color.
   (g) Sulfites will liberate SO_2 which is colorless but has the characteristic, sharp pungent odor of burning sulfur.
   (h) Oxalates, when heated with H_2SO_4, give off CO and CO_2. The CO can be ignited.
   (i) Thiosulfates liberate SO_2 and form a residue of sulfur.
   (j) Acetates heated with H_2SO_4 liberate acetic acid which is recognized by the odor of vinegar.
2. Moisten a gram of the solid in an evaporating dish (if Cu and Ba are absent) with conc. H_2SO_4, add a few drops of alcohol and ignite the alcohol. A green flame indicates borates. If Cu or Ba are present use a test tube fitted with a stopper and short constricted outlet tube instead of the evaporating dish. In either case heat to help expel the volatile ethyl borate which will burn in the alcohol vapor with a green flame.
3. Add cold dilute HCl solution. An immediate evolution of brown fumes indicates nitrites.
4. If the sample is yellow or deep purple in color heat with dilute alcohol.
   (a) If the yellow color is changed to green and the metal analysis shows Cr present then chromates are present.
   (b) If the purple color is discharged and manganese was found in the metal analysis this test indicates the presence of permanganates.
5. The test for phosphates was made at the beginning of the analysis for Group III and need not be repeated at this point.

Preparation of Special Solution for Detection of Acidic Groups.—Take about 2 g of the powdered sample and boil with 25 cc of a saturated solution of sodium carbonate for 15 minutes. If a fusion was made in the analysis for metals, add the water extract from D2, dilute to 40 cc and filter. Use this solution for the following acid tests. Take 20 cc of this "prepared solution," make acid with dilute acetic acid and then add 1 cc of the acid in excess, boil gently to expel CO_2 and any H_2S which might be present. Test the vapor for H_2S by holding a piece of paper moistened with lead acetate in the vapors evolved during the boiling. A dark coloration

AN OUTLINE FOR QUALITATIVE ANALYSIS

indicates sulfides. If a white gelatinous precipitate forms at this point test it for silicic acid by the microcosmic bead test as follows: Filter, ignite the residue in a crucible, make a bead of microcosmic salt, dip it in the residue and fuse. If undissolved particles float in the bead while melted, Si is indicated. Make the filtrate from the procedure above neutral or slightly alkaline. Add a mixture of $Ca(NO_3)_2 + Ba(NO_3)_2$ solution and filter. Precipitate see Group I. Filtrate see Group II.

Precipitate—Group I acids. Add 5 cc acetic acid, warm and stir. Filter. The filtrate contains $CaHPO_4$, $CaC_4H_4O_6$. This filtrate is discarded as these groups were tested for previously.
Residue—CaF_2, CaC_2O_4, $BaSO_4$, $BaCrO_4$. Treat with 5 cc dilute HCl. Filter.

Precipitate—CaF_2, $BaSO_4$. Divide into two parts.

First portion — Add conc. HCl and boil for a few minutes. Dilute White ppt. indicates SO_4''.

Second portion — Dry over a low flame. Mix with a little sand. Place in a test tube and moisten with conc. H_2SO_4. Hold a film of water in a glass loop just above the mixture and warm. A ppt. in the water film indicates fluorides.

Filtrate—If yellow, chromates are present. As confirming this recall whether the filtrate from Group I metals was yellow and then turned green when H_2S was passed in and a formation of colloidal sulfur formed. To test for oxalates take 2 cc of the prepared solution, boil with a small excess of acetic acid, filter, make alkaline with NH_4OH, add $Ca(NO_3)_2$, filter, treat with 5 cc acetic acid, filter, wash. Then treat with dilute H_2SO_4, warm and add dilute $KMnO_4$ solution. Color destroyed indicates C_2O_4''.

Filtrate—Sodium salts of Group II. Make exactly neutral with HNO_3. Add $Zn(NO_3)_2$ solution. Filter.

Precipitate—$Zn_3(FeC_6N_6)_2$ brownish yellow and $Zn_2Fe(CN)_6$ white. Divide into 2 parts.

First pt in NH_4OH. Brown coloration indicates $(FeC_6N_6)''''$.

Second portion—Dissolve in HCl and add $FeCl_3$ solution. Deep blue indicates $(FeC_6N_6)''''$.

Filtrate—Take out a few drops to test for CNS.

To the few drops add $FeCl_3$ soln. Blood red color that remains on heating indicates CNS.

To the remainder of the solution add HNO_3 until acid and then add $AgNO_3$ solution. Filter. Discard filtrate. Add "chloride reagent" (described below). **Filter.

Filtrate—Acidify with HNO_3. White ppt. indicates chlorides.

Precipitate—Place a small amount in a test tube. Add 2 cc CS_2 or CCl_4, then some chlorine water (see below)*. Shake vigorously. Purple color in CS_2 indicates iodine. Brown color in CS_2 indicates bromine. If purple at first, continue to add Cl water until the purple color is discharged. If the brown color presists both iodine and bromine are present.

*Chlorine water for this test should be freshly prepared by adding one or two small crystals of $KClO_3$ to a few cc of dilute hydrochloric acid and then warming the solution.

**Chloride Reagent: Dissolve 1.7 grams of $AgNO_3$ and 25 grams of KNO_3 in an amount of water less than a liter, add 17cc of conc. NH_4OH, and dilute to a liter.

OTHER TESTS FOR ACIDIC CONSTITUENTS

Nitrates—If iodides, bromides, ferrocyanides, ferricyanides, chromates and nitrites are absent, take 2 cc of the "Prepared solution," make just acid with acetic acid, boil, filter if any precipitate forms, add 3 cc of ferrous sulfate solution, then tip the test tube to an angle of 45° and slowly pour a few cc of concentrated H_2SO_4 down the side of the tube. Bring the tube back to an upright position without stirring the contents. A brown ring forming at the

junction of the two layers indicates NO_3'. If any of the acids which interfere with test and which are mentioned above are present they can be removed as follows: make 5 cc of the "prepared solution" as nearly neutral as possible (do not permit the solution to become acid) with acetic acid, boil with 5 cc $(NH_4)_2SO_4$ solution. This removes nitrites. Acidify the boiled solution with H_2SO_4 and add Ag_2SO_4 solution which removes Br', I', $Fe(CN)_6'''$ and $Fe(CN)_6''''$. Filter. To the filtrate add Na_2SO_3 and allow to stand for a few minutes. This reduces the chromates. Boil to expell SO_2, then make alkaline with NH_4OH to precipitate Cr. Filter and test the filtrate as directed above for nitrates $(NO_3)'$.

Sulfides—Some sulfides are left in the residue from boiling the "prepared solution" with acetic acid and do not evolve H_2S in this step. If this residue is placed in a test tube with some sulfur-free zinc and heated with HCl the H_2S will be liberated and can be detected with lead acetate paper.

Phosphates — Arsenates, arsenites, chromates and permanganates are usually detected in the course of the metal analysis.

A few unusual interfering combinations may be met with which because of the nature of this treatise are not discussed.

FLAME TESTS

The substance is heated on a piece of charcoal with a blow-pipe, or held in the outer flame of a Bunsen burner on a loop of platinum wire.

Blue:— *Azure*, Pb, Se, $CuCl_2$ or other copper compounds that have been moistened with hydrochloric acid.
Light blue, As and some of its compounds.
Greenish blue, $CuBr_2$, Sb.

Green:— *Emerald green*, copper compounds other than the halides.
Blue-green, phosphates when moistened with H_2SO_4, B_2O_3.
Faint green, Sb and NH_4 compounds.

White:— *White-green*, Zn.

Red:— *Carmine*, Li compounds. Masked by Ba or Na.
Scarlet or *Crimson*, Sr compounds. Masked by Ba.
Yellow-red, Ca compounds. Masked by Ba.

Violet:— K compounds other than borates, phosphates and silicates. Masked by Na or Li.
Purple-red given by K in the presence of Na when viewed through a blue glass, the blue glass cutting out the yellow caused by Na. Rb and Cs are the same as K compounds.

Yellow:—Na compounds even in small traces. *Caution*—Most compounds contain traces of Na which will color the flame. The appearance of a yellow flame is not a test for Na unless it persists and is not perceptibly increased in intensity on the addition of about 1% of NaCl to the dry compound.

BEAD TESTS

A clear bead is made by fusing a little borax or microcosmic salt on a loop of platinum wire. This bead is touched to the dry unknown material and again held in the flame of a Bunsen burner. The outer part of the flame is the oxidizing flame, while the inner cone is the reducing flame. The abbreviations used below are h., hot; c., cold; *h. c.*, hot or cold; *s.*, saturated; *n. s.*, not saturated; and *sprs.*, supersaturated.

Color of the Bead	Borax Bead, $Na_2B_4O_7\ 10H_2O$		Microcosmic Salt Bead, $NaNH_4HPO_4$	
	Oxidizing Flame	Reducing Flame	Oxidizing Flame	Reducing Flame

ORGANIC REAGENTS FOR DETECTING INORGANIC IONS

Compiled by

THOMAS H. WHITEHEAD, PH. D.

Abbreviations used in the table: AcOH-acetic acid; addn-addition; alc-alcohol or alcoholic; alk-alkaline; amm-ammonia or ammoniacal; aq-aqueous; conc-concentrated; contg-containing; detc-detects; dil-dilute; evap-evaporate; EtOH-95% ethyl alcohol; g-gram; intfr-interfere; mg-milligram; mcg-microgram; ml-milliliter; ppm-parts per million; ppt-precipitate; reag-reagent; satd-saturated; sepg-separating; sl-slight; soln-solution; xs-excess.

Use of this table: The purpose of this table is to provide a useful set of tests for the detection of inorganic substances for those not having access to a large library. For the common cations and anions, and for the separation of interfering ions reference should be made to *An Outline for Qualitative Analysis* on the preceding pages of this Handbook. For the less common ions reference may be made to Noyes and Bray, "System of Qualitative Analysis for the Rare Elements," The Macmillan Company, New York, 1927, reprinted 1948. If these are followed, methods for preparing test solutions will be facilitated.

References: In addition to the references mentioned above, several relatively inexpensive books are listed below which contain a wealth of information on reagents, tests, and original sources of information in the chemical literature. This additional information will often make possible an extension of these tests to quantitative determinations. Because Chemical Abstracts (*C. A.*) and the Journal of the American Chemical Society (*J. A. C. S.*) are widely available many references have been made to them also.

Feigl, "Qualitative Analysis by Spot Tests," translated by J. Matthews, Second English Ed., Nordeman, New York, 1939.

Snell and Snell, "Colorimetric Methods of Analysis," Vol. I, Second Ed., D. Van Nostrand Company, New York, 1949.

Welcher, "Organic Analytical Reagents," Vols. I, II, III, IV, D. Van Nostrand Company, New York, 1947–48.

Sources of reagents: To simplify the purchase of organic reagents, reference is made to each reagent by citing its code number (*EK*) of the Eastman Kodak Co., Distillation Products Division, Rochester 3, N. Y., and (*M*) of the Matheson, Coleman and Bell, Inc., East Rutherford, New Jersey. For example: Thymol (EK 248; M 2510). By reference to the catalogs of these suppliers, name, formula, melting point, boiling range, and purity can be verified. Synonyms are given for those chemicals having more than one name.

ACETATE

Reagent: Satd soln of *o*-nitrobenzaldehyde (EK 2559; M 6689) in 2 *N* NaOH soln.

Test soln: Prepare soln as directed for anions*.

Procedure: Place 1 g of CaO in a test tube, add 2 ml of test soln. Moisten a piece of filter paper with reag soln. Fit this over the mouth of the test tube, then warm the test tube. If acetate was present, acetone is formed and produces a spot of blue color on the paper.

Sensitivity: 4 mg acetate per 100 ml of soln.

Interferences: None reported.

References: Feigl, p. 331; Welcher, Vol. I, p 386.

ALUMINUM

Reagent: An aq 0.1% soln of aurin tricarboxylic acid ammonium salt; "Aluminon;" (EK P4468; M P2243).

* See Outline for Qualitative Analysis.

Test soln: Dissolve in 1 *N* HCl 0.1 *g* of the ppt in Group III* which is believed to contain $Al(OH)_3$.

Procedure: To 2 ml of the test soln, add 1 ml of 3 *N* NH_4OAc and 1 ml of reag soln. Shake well and add 1 ml of 3 *N* $(NH_4)_2CO_3$ soln. A red ppt forms if Al is present.

Sensitivity: A soln which is 2×10^{-5} molar with respect to Al^{3+} gives a ppt; one which is 1×10^{-6} molar gives a red color.

Interferences: Heavy metal ions intfr, if present. Zn^{++} gives a red ppt but this red color is removed by washing with H_2O. Ba^{++}, Ca^{++}, Sr^{++} in large amounts intfr but $(NH_4)_2CO_3$ soln prevents this.

References: Welcher, Vol. I, p 101; J. A. C. S., 47, 142 (1925).

AMMONIA, AMMONIUM

Reagent: An alc 25% soln of thymol (EK 248; M 2510).

Test soln: To 5 ml of unknown soln add 4 *N* NaOH until alk. Distil and catch distillate of amm in 2 ml of 0.1 *N* HCl.

Procedure: To 1 ml of test soln, add 4 drops of reag soln, shake, then add 2.5 ml of Br_2 water and 1.2 ml of 2 *N* NaOH soln. Shake and let stand for 3 min. Add 2 ml of xylene and shake. Red to violet color forms in the xylene layer if amm is present.

Sensitivity: 0.01 mg NH_3 per 100 ml of soln.

Interferences: None with this procedure.

References: Welcher, Vol. I, p 187.

ANTIMONY

Reagent: An aq 0.02% soln of Rhodamine B (EK P4453; M B394).

Test soln: Take 0.5 ml of the soln containing Sb and Sn as chlorides from Group II*. Add 1 drop of satd soln of KNO_2 to oxidize Sb^{3+} to Sb^{5+}.

Procedure: To 0.5 ml of the test soln, add 1–4 drops of reag soln until the soln is colored. A red to violet color is formed if Sb is present.

Sensitivity: 1 mcg per ml of soln.

Interferences: Sn does not intfr but Bi^{3+}, Hg^{++}, and WO_4^{2-} do.

References: Welcher, Vol. IV, p 550; C. A., 41, 5913 (1947).

ARSENIC

Reagent: An aq 0.5% soln of *N*-ethyl-8-hydroxytetrahydroquinoline hydrochloride; "Karin A." For preparation see Welcher, Vol. I, p 330; Beilstein, XXI, 64; *Ber.*, 16, 717 (1883).

Procedure: Place a drop of soln contg the As as arsenite on a strip of filter paper and moisten this with a drop of conc HCl. Add a drop of reag soln and a drop of 1% $FeCl_3$ soln. Carefully warm the paper. A reddish-brown coloration appears if As is present.

Sensitivity: 0.1 mcg per ml of soln. Extreme limit, 0.0006 mcg As.

Interferences: Hg, Pb, Cu intfr. Arsenate, Sb, Bi, Al, Cr, Co, Ni, Ca, Sr, and Ba do not.

References: Welcher, Vol. I, p 330; C. A., 29, 5037 (1935).

BARIUM

Reagent: An aq 5% soln of sodium rhodizonate (M 5302).

Test soln: Filter off the ppt of alkaline earth carbonates and wash several times with water. Use the washed ppt for the test.

Procedure: Transfer 0.1 *g* of ppt to a clean filter paper. Add 3 drops of reag soln. A red-brown color forms if $BaCO_3$ is present. Add 1 drop 1 *N* HCl to this spot. The color changes to bright red if Ba^{++} is present.

Sensitivity: 2.5 mg Ba^{++} per 250 ml of soln.

* See Outline for Qualitative Analysis.

Interferences: Ca, Sr, and Mg do not interfere.
Reference: Welcher, Vol. I, p 221.

BERYLLIUM

Reagent: An alc 0.1% soln of curcumin (EK 1179).
Test soln: Dissolve the ppt of $Be(OH)_2$ and $Al(OH)_3$ in the least amount of 6 *N* HCl required. Dil to 10 ml with H_2O. Add xs of solid NaF. Let stand for 1 hr. Filter and use filtrate.
Procedure: To 10 ml of test soln, add 1 drop of reag soln, 0.5 ml of 4 *N* NH_4Cl, and 6–8 drops of 4 *N* amm. A red ppt forms if Be^{++} is present.
Sensitivity: 50 mg Be^{++} per liter.
Interferences: None if this procedure is followed.
References: Welcher, Vol. IV, p 396; J. A. C. S., **50**, 393 (1928).

BISMUTH

Reagent: A satd soln of thiourea (EK 497; M CB798) in 1 *N* HNO_3 (sp g. 1.025–1.030).
Test soln: To 0.1 g ppt containing $Bi(OH)_3$ from Group II*, add the least amount of 1 *N* HNO_3 to dissolve it.
Procedure: To test soln, add reag soln dropwise until no more ppt forms. A yellow color appears in soln if Bi^{3+} is present.
Sensitivity: 10 ppm.
Interferences: None if this procedure is followed.
Reference: Welcher, Vol. IV, p 178.

BORON, BORATE

Reagent: An alc 0.1% soln of curcumin (EK 1179).
Test soln: Take 5 ml of "prepared soln" for acidic constituents*, acidify with conc HCl and evap to dryness in a porcelain dish. Dissolve the residue in 3 ml of 3 *N* HCl.
Procedure: To 3 ml of this soln, add 5 drops of reag soln and evap almost to dryness. Cool. A red color forms if borate is present. Moisten with 2 drops of 1 *N* NaOH. Color changes to blue if borate is present.
Sensitivity: 1 ppm.
Interferences: Oxidizing anions intfr but are removed by the procedure above. Fe, Mo, Ti, Nb, Ta, and Zr intfr but are removed in the "prepared soln."
References: Welcher, Vol. IV, p 397; Feigl, p 223.

BROMINE, BROMIDE

Reagent: A satd soln of fluorescein (EK 780; M B297) in 1:1 alc-H_2O mixture.
Test soln: Put 1 ml of unknown soln in a small test tube, acidify with conc AcOH, then add 0.1 g solid PbO_2.
Procedure: Moisten filter paper with reag soln and place this over the test tube. Warm the bottom of the tube gently with a flame. A red spot forms on the filter paper if Br or I are present.
Interferences: Iodine and iodides intfr. To remove them, add 2 ml of CCl_4 to 2 ml of unknown soln, then 1 drop of conc AcOH, pass in Cl_2 gas and shake until I_2 is in the CCl_4 layer. Decant 1 ml of the aq layer and test for Br as above.
References: Welcher, Vol. IV, p 448; C. A., **19**, 1828 (1925).

CADMIUM

Reagent: A soln of 0.2 g of 2,2′-bipyridyl (EK 4397; M 5209) and 0.146 g of $FeSO_4 \cdot 5H_2O$ in 50 ml in water; add 10 g KI, shake well over a 30 min period. Filter and use filtrate.

* See Outline for Qualitative Analysis.

Test soln: To the Group II* soln contg hydroxides of Bi, Cu, and Cd add conc amm in sl xs and filter. Use filtrate for test.

Procedure: Place a piece of quantitative filter paper (such as Whatman, No. 40) over a 50 ml beaker. Put 1 drop of test soln on the paper and immediately add 1 drop of reag soln. A red ppt forms if Cd^{++} is present.

Sensitivity: 1 ppm.

Interferences: Pb, Hg, Bi, Sn, and Ag intfr if present. $Cu(NH_3)_4^{++}$ and $Zn(NH_3)_4^{++}$ do not. Procedure above removes intfr.

Reference: Welcher, Vol. III, p 81.

CALCIUM

Reagent: Dissolve 2.2 g of 8-hydroxy-7-iodo-5-quinoline sulfonic acid; "Loretin;" (EK 4449) in 50 ml H_2O and add 1.6 ml of 4 *N* NaOH. Dilute to 65 ml with H_2O.

Test soln: After removing Groups I, II, III*, and Ba^{++} and Sr^{++} in Group IV, dissolve the calcium ppt in 6 *N* HCl and evap to 2.5 ml volume. This should not contain more than 2% Ca; dil if necessary.

Procedure: Prepare a buffer mixture by mixing 80 ml of 30% AcOH, 10 g AcONa, and dil to 100 ml with H_2O. Mix 2.5 ml of this buffer soln with 2.5 ml of the test soln. Heat 25 ml of reag soln to boiling and add it to the buffered test soln. Shake well and then heat on water bath for 15 min. An orange ppt forms if Ca^{++} is present.

Sensitivity: 5 mg of Ca per liter of soln.

Interferences: Ba and Sr intfr. Mg, Na, K, and NH_4^+ do not.

References: Welcher, Vol. I, p 336; C. A., 33, 5767 (1939).

CERIUM

Reagent: An aq soln of 0.02% gallic acid (EK T142; M CB403).

Test soln: Ppt contg $Ce(OH)_3$ is dissolved in 3 *N* HNO_3 and diluted to give a soln contg about 2×10^{-4} *M* of Ce^{3+}.

Procedure: Mix 2.7 ml of reag soln with 2.7 ml of test soln, then add 2 ml of diethyl ether; finally add 5.3 ml of 0.1 *M* amm. A blue-violet color forms if Ce^{3+} is present.

Sensitivity: 1.4×10^{-4} mg Ce per ml.

Interferences: Th, La, and Ti intfr. These are removed by the procedure of Noyes and Bray, p 210.

Reference: Welcher. Vol. I, p 203.

CESIUM

Reagent: A formic acid soln of 0.5% 2,4-dinitro-1-naphthol-7-sulfonic acid sodium salt; "Naphthol Yellow S;" (EK 1393; M B356).

Test soln: An aq soln of CsCl contg at least 3 mg per ml.

Procedure: If necessary, make 2 ml of the test soln neutral to litmus with amm. To 1 drop of test soln add 1–3 drops reag soln. Yellow needles form if Cs^+ is present.

Sensitivity: 3 mg of Cs per ml.

Interferences: Tl^+, Hg^{++}, Sn^{++}, Ag^+, Pb^{++}, Cu^{++}, and Rb^+ intfr. All but Rb^+ are removed by usual qualitative procedures. To remove Rb^+ see Noyes and Bray, p 250.

Reference: Welcher, Vol. IV, p 20.

CHLORATE

Reagent: An aq soln of 0.1% aniline sulfate (EK 502; M 6188) or a soln prepared by adding 1 ml aniline to 1 liter H_2O and then adding conc H_2SO_4 dropwise until the aniline dissolves.

Test soln: Acidify 2 ml of "prepared soln" for acidic constituents* with HNO_3.

* See Outline for Qualitative Analysis.

If other oxidizing anions are present, remove them with $Ba(NO_3)_2$ and then with $AgNO_3$. Take 1 ml of filtrate for test.

Procedure: To 1 ml of test soln, add 5 drops of reag soln, then underlay with 3 ml of conc H_2SO_4. A blue color at interface forms if chlorate is present.

Sensitivity: 0.05 mg chlorate per ml of soln.

Interferences: Nitrates and iodates give a brownish-red color. Chromates must be absent and must be removed with $AgNO_3$ as stated above.

Reference: Welcher, Vol. II, p 267.

CHLORINE

Reagent: Mix 2 ml of aniline (EK 25; M CB162) and 4 ml H_2O; then add 12 *M* HCl dropwise until the aniline dissolves.

Test soln: Heat unknown soln and use vapor for test.

Procedure: Moisten filter paper with reag soln and expose it to the vapors from the test soln. Paper turns wine-red from Cl_2 vapor and this color changes to blue on further exposure to air.

Interference: N_2O gives a yellow-brown color changing to green-blue in air.

Reference: Welcher, Vol. II, p 272.

PERCHLORATE

Reagent: Mix 0.1 ml of 1.6% aq soln of methylene blue (EK 573; M B698) with 25 ml of 50% aq soln of crystallized $ZnSO_4$.

Test soln: Neutralize 2 ml of "prepared soln" for acidic constituents* with 3 *N* H_2SO_4.

Procedure: To 0.2 ml of test soln, add 0.1 ml of a 40% aq soln of KNO_3. Add 5 ml of reag soln and mix well. A violet color forms if ClO_4^- is present. Compare this color with that formed in a soln known to contain $NaClO_4$ or $HClO_4$.

Sensitivity: 0.01 mg ClO_4^- per ml of soln.

Interferences: Iodides intfr but can be removed with Ag_2O. Chromates intfr but can be removed with neutral $Pb(OAc)_2$. Other anions do not intfr.

References: Welcher, Vol. IV, p 523; C. A., **22**, 2723 (1928).

CHROMIUM, CHROMATE

Reagent: Dissolve 0.2 g of 1,5-diphenylcarbohydrazide; "Diphenylcarbazide;" (EK 618; M 1344) in 10 ml of glacial AcOH and then dilute to 100 ml with 95% EtOH.

Test soln: Acidify with H_2SO_4 the soln from Group III* which contains Cr as Na_2CrO_4; or acidify an unknown soln believed to contain CrO_4^{2-}

Procedure: To 2 ml of test soln, add 3–5 drops of reag soln. A reddish-violet color forms if CrO_4^{2-} is present.

Sensitivity: 1 ppm of CrO_4^{2-}.

Interferences: Co, MnO_2, Ni, and Cu intfr. These are removed by the usual qualitative procedures.

References: Welcher, Vol. III, p 435; C. A., **37**, 3690 (1943).

COBALT

Reagent: An aq soln of 0.5% 1-nitroso-2-naphthol-3, 6-disulfonic acid disodium salt; "Nitroso-R salt;" (EK P1124; M CB537).

Test soln: Neutralize with amm the aqua regia soln of Co^{++} and Ni^{++} from Group III*.

Procedure: To 2 ml of test soln, add 1 g NaOAc and then 2 ml of reag soln. Heat to

* See Outline for Qualitative Analysis.

boiling, add 1 ml of conc HNO_3, and boil for 1 min. A deep red color forms if Co^{++} is present.

Sensitivity: 0.03 mg Co^{++} per ml of soln.

Interferences: If the amount of Co^{++} is very low, concentrations more than 0.1 *M* of Ni^{++}, Cr^{+++}, and Cu^{++} intfr. If present, these may be removed easily.

References: Welcher, Vol. III, p 332; Feigl, p 38.

COPPER

Reagent: An alc soln of 5% α-benzoinoxime; "Cupron;" (EK 1877; M 2253).

Test soln: Make the unknown soln acid to litmus with dil HCl. If large amounts of other ions pptd by amm are present, evap to dryness and ignite to remove xs amm salts and xs tartrate. Dissolve the ignited residue in dil HCl.

Procedure: Place a drop of test soln on filter paper, add 1 drop of reag soln and hold over a bottle of conc amm. A green color appears if Cu is present.

Sensitivity: 2 ppm in soln.

Interferences: None if the procedure above is followed.

References: Welcher, Vol. IV, p 241; Feigl, p 38.

CYANIDE

Reagent: (*a*) Mix 47.5 ml of a satd soln of benzidine (EK 33; M CB211) in AcOH with 52.5 ml H_2O. (*b*) Dissolve 0.286 g of cupric acetate in H_2O and dilute to 100 ml.

Test soln: Take 5 ml of "prepared soln" for acidic constituents* or original unknown soln and make acid to litmus with H_3PO_4.

Procedure: Mix 1 drop of reag soln *b* with 5 drops of reag soln *a* and add 0.5 ml of H_2O. Bubble CO_2 gas through the test soln and deliver the evolved gas into the reag soln. In this manner any HCN present in the test soln is swept out and transferred into the reag soln. A blue ppt forms in the reag soln if cyanide is present.

Sensitivity: 0.25 mcg HCN per ml of soln.

Interferences: None reported.

Reference: Welcher, Vol. II, p 315.

GALLIUM

Reagent: An alc soln of 5% 3,5,7,2′,4′-pentahydroxyflavone; "Morin;" (EK T4475; M T7429).

Test soln: Use an original unknown soln or dissolve the aluminum group ppt from Group III* in AcOH.

Procedure: To 5 ml of soln acid with AcOH, add reag soln dropwise until soln is colored. An intense green fluorescence is given by Ga.

Sensitivity: 1 part in 6,000,000 parts of soln.

Interferences: Al^{3+} gives a similar color but this color is removed by adding NaF soln. Aluminum and gallium can be separated by the procedure given in Noyes and Bray, p 151. Indium (see this) also interferes.

Reference: Welcher, Vol. IV, p 374.

GERMANIUM

Reagent: An H_2SO_4 soln of 0.01% quinalizarin (EK 2787; M 5652).

Test soln: Dissolve 0.1 g of solid unknown in 5 ml conc H_2SO_4. If the unknown is in soln, evap to dryness on the water bath and then redissolve the residue in 5 ml conc H_2SO_4.

Procedure: Warm 1 ml reag soln with 1 ml of test soln. A violet color is given by Ge.

* See Outline for Qualitative Analysis.

Sensitivity: 5 mg Ge per ml of soln.

Interference: Boron intfrs. Ge can be separated from boron by pptg GeS_2 from 4 *N* H_2SO_4 soln with H_2S. See Noyes and Bray, p 62.

Reference: Welcher, Vol. IV, p 465.

GOLD

Reagent: Mix 1 ml of an alc soln of 0.03% 5(*p*-dimethylaminobenzylidene)-rhodanine; "Dimethylaminobenzalrhodanine;" (EK 2748; M 4203), with 13 ml of benzene and dil to 50 ml with chloroform.

Test soln: Unless acid already, make unknown soln acid to litmus with HNO_3.

Procedure: To 5 ml test soln add 1 ml of reag soln. The organic layer changes from yellow to pink-violet if Au is present.

Sensitivity: 0.1 mcg Au in 5 ml of soln.

Interferences: Ag, Hg, Pt, and Pd intfr. These can be separated. See Noyes and Bray, p 110.

Reference: Welcher, Vol. III, p 423.

INDIUM

Reagent: An alc soln of 0.02% 3,5,7,2',4'-pentahydroxyflavone; "Morin;" (EK T4475; M T7429). See reag for Gallium.

Test soln: Make unknown soln sl acid with dil HNO_3.

Procedure: To 2 ml of test soln add reag dropwise until soln is colored. An intense green fluorescence is given by In, Ga, Al, and Sc. Add 5 drops of a satd aq soln of NaF which removes the fluorescence due to Al and Sc. If fluorescence remains, saturate soln with H_2S and filter. Fluorescence due to In disappears but Ga shows fluorescence in filtrate.

Sensitivity: 1 mcg In^{3+} per ml of soln.

References: Welcher, Vol. IV, p 375; C. A., **32**, 1606 (1938).

IODINE, IODIDE

Reagent: Make a paste of 2 g soluble starch (EK P1284; M CB776) in 30 ml of cold H_2O and add this slowly to 70 ml of boiling H_2O. Boil for 5 min.

Test soln: To 10 ml of unknown soln add dil AcOH until just acid.

Procedure: Add 5 ml of an aq 10% KI soln to 10 ml of test soln. Shake and add 1 ml reag soln. A blue color forms if I_2 is present.

Procedure for iodide: To 10 ml of test soln add amm until alkaline to litmus. Then add 1 ml of 3% soln of H_2O_2 and warm. Add 4 *N* H_2SO_4 until just acid. Now add 1 ml reag soln. A blue color forms if I^- is present.

Sensitivity: 5 mcg per ml of soln.

Interferences: None reported.

References: Welcher, Vol. IV, p 284; J. A. C. S., **52**, 2768 (1930).

IRIDIUM

Reagent: A glacial AcOH soln of 1% leuco-malachite green. For preparation of leuco-malachite green see Welcher or Beilstein, XIII, 275.

Test soln: If the unknown is in soln, use as is; if solid, dissolve in aqua regia and make very dilute with H_2O.

Procedure: Add 5 drops of reag soln to 10 ml of test soln. A green color appears at once if $IrCl_6^{2-}$ is present.

Sensitivity: 1 part Ir in 6,000,000 parts of soln.

Interferences: Cl_2, $FeCl_3$, and H_2PdCl_6 intfr. H_2PtCl_6, H_3RhCl_6, and H_2OsCl_6 do not. Interfering substances are easily removed; see Noyes and Bray, p 110.

References: Welcher, Vol. IV, p 513; C. A., **24**, 2689 (1930).

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

IRON

Reagent: An alc soln of 2% 2,2'-bipyridine; "Dipyridyl;" (EK 4397; M 5209).
Test soln: Make unknown soln acid to litmus with dil H_2SO_4.
Procedure: To 0.5 ml of test soln, add 0.1 g sodium sulfite and shake. If any yellow color persists, add sodium sulfite until it disappears. Add 2 drops of reag soln. Shake. A pink to red color forms if Fe^{3+} is present.
Sensitivity: 0.001 mcg Fe per ml of soln.
Interferences: Cuprous salts intfr and must be removed. Large amounts of Fe^{3+} intfr unless sodium sulfite is added, or a satd soln of KF added until the yellow color fades. With the addition of KF, Fe^{++} can be detected in the presence of Fe^{3+}.
References: Welcher, Vol. III, p 73; C. A., 38, 6228 (1944).

LANTHANUM

Reagent: A soln of 4% 8-hydroxyquinoline; "8-Quinolinol;" (EK 794; M 2759) in 8% AcOH.
Test soln: Use AcOH soln of rare earths (Noyes and Bray, p 210) or the original unknown soln acidified with AcOH.
Procedure: To 5 ml of test soln, add 5 ml of reag soln and shake well. Make alk with xs amm. A white ppt forms if La^{3+} is present.
Sensitivity: Not reported except as very sensitive.
Interferences: Other rare earths do not intfr. Metallic ions which ppt with 8-hydroxyquinoline or xs amm intfr. These are removed by the procedure of Noyes and Bray.
References: Welcher, Vol. I, p 311; C. A., 31, 967 (1937).

LEAD

Reagent: Dissolve 10 mg diphenylthiocarbazone; "Dithizone;" (EK 3092; M 4205) in 250 ml CCl_4. This soln must be prepared not more than a few days before use and kept in a brown bottle.
Test soln: Make 1 ml of the unknown soln acid to litmus with 1 *N* H_2SO_4 and dilute to 100 ml with distilled water.
Procedure: To 5 ml of the test soln add 2 ml of 1 *N* H_2SO_4. Shake this with 5 ml of reag soln in a separatory funnel. Remove the CCl_4 layer. A red color in the CCl_4 layer is given by Pb^{++}, Sn^{++}, and Tl^{+}. Wash the CCl_4 soln with two 5 ml portions of aq 1% KCN soln. A red color remains in the CCl_4 if Pb^{++} is present.
Sensitivity: About 2 mcg of Pb per ml of soln.
Interferences: Sn^{++} and Tl^{+} intfr but are removed as above.
References: Welcher, Vol. III, p 410; C. A., 35, 46 (1941).

LITHIUM

Reagent: Dissolve 0.1 g of 1-amino-4-hydroxyanthraquinone (EK P6248) in 100 ml of 95% EtOH. Warm, if necessary, to dissolve.
Test soln: Dissolve the solid residue from Group V* in 100 ml of H_2O or if the unknown is a soln, add xs amm, boil to expel xs amm, filter, and use filtrate for test soln.
Procedure: Place 0.1 ml of test soln in a test tube and add 1 ml of 2.5 *N* NaOH soln. Dilute to 10 ml with H_2O and add 0.5 ml reag soln. If Li is present, the soln is purple but when subjected to ultraviolet light it shows an intense red fluorescence.
Sensitivity: 7 mcg per 10 ml of soln.
Interferences: Be^{++} and Ca^{++} intfr. Oxidizing anions affect reag soln and must be removed. Na^{+}, K^{+}, and NH_4^{+} do not intfr.
References: Welcher, Vol. IV, p 442; C. A., 36, 55 (1942).

* See Outline for Qualitative Analysis.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

MAGNESIUM

Reagent: Dissolve 0.5 g of 4-(*p*-nitrophenylazo)resorcinol; "*p*-Nitrobenzeneazoresorcinol;" (EK 2484; M 1193) in 100 ml of 1% NaOH soln.

Procedure: Evap unknown soln to dryness in a porcelain dish, then add 5–10 ml of 6 *N* NaOH soln; stir well. Add 1 drop of reag soln and let stand 10 sec. A blue stain forms if Mg^{++} is present. This turns green with added H_2O but is not affected by conc amm alone.

Sensitivity: 3 mcg Mg per ml of soln.

Interferences: Co^{++}, Ni^{++}, Zn^{++}, and Be^{++} intfr and must be removed. Tartrates, acetate, and citrates intfr but can be removed by ignition.

Reference: Welcher, Vol. IV, p 383.

MANGANESE

Reagent: Dissolve 2 g of hydroxylamine hydrochloride and 1 ml of a 40% soln of formaldehyde in 50 ml of H_2O. These react to form formaldoxime.

Test soln: Use the soln from Group III* containing Mn, Fe, Al, Cr, and Zn. To 10 ml of this soln add 0.1 g of ZnO and shake well. Filter and use filtrate for test soln.

Procedure: To 10 ml of test soln add 1 drop of reag soln. Then add dropwise a soln of 10 *N* NaOH until the soln is alk to litmus. A purple color forms if Mn^{++} is present.

Sensitivity: 0.02 mg Mn^{++} per liter of soln.

References: Welcher, Vol. III, p 346; C. A., **36**, 3450 (1942).

MERCURY

Reagent: A satd soln of *s*-diphenylcarbazide (EK 618; M 1344) in 90% EtOH.

Test soln: Take the ppt from Group II* which may contain HgS and dissolve it in aqua regia. Dilute this with an equal volume of H_2O.

Procedure: To 2 ml of test soln add 3 drops of reag soln and then xs of solid Na_2CO_3. A deep blue color forms if Hg^{++} is present.

Sensitivity: 0.8 mg Hg per liter of soln.

Interferences: Cu^{++} and Zn^{++} do not intfr if the procedure above is followed.

References: Welcher, Vol. III, p 437; C. A., **24**, 566 (1930).

MOLYBDENUM

Reagent: Dissolve 1 g of freshly distilled phenylhydrazine (EK 329; M 2479) in 70 ml of 50% AcOH.

Test soln: If the unknown is in soln, use as is; if a solid, dissolve in aqua regia and dil with H_2O to make it a dil soln; if the unknown is insoluble in aqua regia, follow procedure of Noyes and Bray, p 21, to prepare a soln for testing.

Procedure: Mix 10 ml of test soln with 5 ml of reag soln and boil gently for 1–2 min. A red color forms if molybdate ion is present. The color may be concentrated by extracting with chloroform.

Sensitivity: 100 ppm of Mo.

Interferences: W, V, As, Sb, Cr, Sn, Fe, Mn and U do not intfr.

Reference: Welcher, Vol. II, p 443.

NICKEL

Reagent: An alc soln of 1% diacetyldioxime; "Dimethylglyoxime;" (EK 98; M CB366).

Test soln: To the ppt from Group III* contg CoS and NiS, add enough aqua regia to dissolve, then dil this with 5 parts H_2O, and neutralize with amm.

* See Outline for Qualitative Analysis.

Procedure: To 5 ml of test soln add 1 ml of reag soln and shake. A red ppt forms if Ni^{++} is present.

Sensitivity: 3–4 ppm of Ni.

Interference: Pd^{++} intfr but this may be removed by procedure of Noyes and Bray, p 110.

Reference: Welcher, Vol. III, p 173.

NITRATE, NITRITE

Reagent: Dissolve 0.01 g diphenylbenzidine (EK 1797; M 7378) in 50 ml of conc H_2SO_4 which is free of HNO_3. Heating the H_2SO_4 will remove HNO_3. The reag soln has a stability of one week only and so must be prepared just prior to use.

Test soln: Use an aq soln of unknown or a "prepared soln" for acidic constituents* which has been neutralized with H_2SO_4.

Procedure: Mix 0.5 ml of test soln with 1.3 ml of pure H_2SO_4 in a small porcelain dish. Then add 0.5 ml of reag soln. A blue color forms if either nitrate or nitrite is present.

Interferences: Oxidizing anions must be removed by pptn with Ag_2SO_4 soln before making the test.

Procedure for nitrite: To 1 ml of distilled H_2O, add 1 drop of an aq soln of 0.5% α-naphthylamine (EK 173) and 1 drop of an aq soln of 0.5% sulfanilic acid (EK 238). Then add 1 drop of 4 *N* AcOH and 2 drops of test soln. The formation of a red color is specific for nitrite ion. This test detects 1 part NO_2^- per billion of soln.

Reference: Welcher, Vol. II, p 371, p 405.

NIOBIUM (COLUMBIUM)

Reagent: An aq soln of 1% tannin; "Tannic acid;" (EK P422; M CB792).

Test soln: Fuse the powdered material with KOH, dissolve in 20 parts of H_2O and filter at once. Wash the undissolved material with warm, dil KOH. Add an xs of cold, conc HCl until the material dissolves and use this soln for the test. If the unknown is a soln, make it acid with dil HCl.

Procedure: Add reag soln to 5 ml of test soln until the latter is colored. A reddish-brown color is given by Nb and Ta.

Sensitivity: Reported as very sensitive.

Interference: Ta intfr but may be removed by procedure of Noyes and Bray, p 79, or C. A., **23**, 55 (1929).

References: Welcher, Vol. II, p 153; Noyes and Bray, p 79; C. A., **23**, 55 (1929).

OSMIUM

Reagent: Dissolve 0.05 g of benzidine (EK 33; M CB211) in 10 ml of AcOH and dil to 100 ml with H_2O.

Test soln: Use unknown or if the unknown is a solid dissolve it by the procedure of Noyes and Bray, p 33.

Procedure: Put 2 ml of test soln in a test tube fitted with a stopper carrying a glass delivery tube which has been drawn down to a fine opening. Moisten a piece of filter paper with reag soln. Heat the test tube and allow the vapors to impinge on a spot of the filter paper. If Os is present, a blue color forms on the paper within 30 sec.

Sensitivity: 0.08 mcg in 0.001 ml of soln.

Reference: Welcher, Vol. II, p 288.

OXALATE

Reagent: Dissolve 0.01 g of 2,7-naphthalenediol; "2,7-Dihydroxynaphthalene;" (EK 4408) in 100 ml of conc H_2SO_4.

* See Outline for Qualitative Analysis.

Test soln: Neutralize 5 ml of "prepared soln" for acidic constituents* with 2 *N* H_2SO_4. Add a satd soln of $CaSO_4$ until pptn of calcium oxalate is complete. Filter and wash the ppt twice with 10 ml of H_2O. Add 2 *N* H_2SO_4 to ppt on the filter and catch the filtrate for use as test soln.

Procedure: Put one drop of test soln in a dry test tube and add a small amount of Mg powder until a slight xs remains. Add 2 ml of reag soln and put test tube in boiling water for 15–20 min. A red to violet color forms if oxalate is present.

Sensitivity: 1 part in 50,000 parts of soln.

Interference: Glycolic acid intfr.

References: Feigl, p 336; C. A., **26**, 4769 (1932).

OXYGEN

(*a*) Oxygen in Gaseous Mixtures

Reagent: A soln of 1% diphenylamine (EK 105; M 2823) in conc H_2SO_4.

Test soln: Unknown gaseous mixture.

Procedure: Put 1 ml of H_2O in a strong 250 ml wide mouth bottle. Attach a piece of filter paper to inner wall with a drop of reag soln. Close mouth of bottle with a two-hole rubber stopper carrying a glass inlet tube and a second tube connected to a manometer. Evacuate to 12 mm gauge pressure and hold it until H_2O evaporates from the bottle. Admit nitric oxide gas until the pressure rises to 400 mm. No color should appear on the paper in the bottle. Now admit the gaseous unknown. A blue color appears on the paper within 2 min if gas contains as much as 0.01% by volume of O_2.

Interferences: None reported.

References: Welcher, Vol. II, p 365; C. A., **20**, 26 (1926).

(*b*) Oxygen Dissolved in Water or Aqueous Solutions

Reagent: (*a*) An aq soln of 13% 2,4-diaminophenol hydrochloride; "Amidol;" (EK P614; M P5190). (*b*) An aq soln of 75% sodium citrate.

Test soln: Water or an aq soln.

Procedure: To the sample in a 2 ounce bottle, add 1 ml of reag soln *b* and 2 ml of reag soln *a*. Mix well and allow to stand for 30 min. A red color forms if 1 ppm of O_2 is in soln.

Interferences: Over 1.5 ppm Cl_2, 5 ppm Fe^{3+}, 2 ppm NO_2^-, and 5 ppm H_2S intfr. Organic matter does not intfr.

Reference: C. A., **30**, 198 (1936).

PALLADIUM

Reagent: Dissolve 25 mg of *p*-nitrosodiphenylamine (EK 1127) in 50 ml alc, and dil to 100 ml with H_2O. Filter, if any solid remains.

Test soln: An aq soln of the unknown.

Procedure: To 25 ml of 1 *N* AcONa soln, add HNO_3 until pH is 1.2 when measured with a pH meter. Now add 15 ml of test soln and 2 ml of reag soln, and dil to 100 ml with H_2O. Allow to stand for 30 min. A deep red color forms if Pd^{++} is present.

Sensitivity: 50 mcg Pd per ml of soln.

Interferences: Au, Ag, and Cu intfr.

References: Welcher, Vol. III, p 409; C. A., **33**, 7691 (1939).

PHOSPHORUS, PHOSPHATE

Reagent: (*a*) Dissolve 0.05 g benzidine (EK 33; M CB211) in 10 ml glacial AcOH, and dil to 100 ml with H_2O. (*b*) Dissolve 5 g ammonium molybdate in 100 ml of cold H_2O and pour this soln into 35 ml of 6.6 *N* HNO_3.

Test soln: An aq soln of the unknown.

* See Outline for Qualitative Analysis.

Procedure: Add 3 drops of reag soln *b* to 2 ml of test soln, then add 3–5 drops of reag soln *a*. Shake and add 1% amm soln until a faint turbidity persists. A blue color forms if phosphate is present.

Sensitivity: 0.00066 mg of P as P_2O_5 per ml of soln.

Interference: Oxalate intfr but addition of more of reag soln *b* will overcome this.

Reference: Welcher, Vol. II, p 293.

PLATINUM

Reagent: An aq soln of 10% resorcinol (EK 222; M 2869). This soln will not keep and must be prepared just prior to use.

Test soln: If the unknown is a solid put 0.5 g in a porcelain dish; if a liquid, evap to dryness in a porcelain dish. Treat the solid with 10 ml of aqua regia and warm until soln occurs. Dil to 30 ml with H_2O. Shake twice with 10 ml portions of ethyl acetate and discard the ethyl acetate. Evap the aq soln to dryness, redissolve in 1 ml H_2O and sat with NH_4Cl. Filter and dissolve the ppt of $(NH_4)_2PtCl_6$ + $(NH_4)_2IrCl_6$ in 5 ml aqua regia, evap to dryness, add 10 ml conc HCl and 2 ml conc HNO_3, and again evap to dryness. Add 5 ml H_2O and then enough 1 *M* $NaHCO_3$ until alk to litmus. Heat on a water bath, add 1 ml satd aq Br_2 soln and 0.5 ml 1 *M* $NaHCO_3$ soln. Filter and use filtrate for test soln.

Procedure: To 1 ml reag soln add 1 ml of test soln and 2 ml of a 10% soln of amm. A garnet-red color forms if Pt is present.

Sensitivity: Very sensitive.

Interferences: None.

References: Welcher, Vol. I, p 177; C. A., **21**, 1605 (1927); Noyes and Bray, p 113–124.

POTASSIUM

Reagent: An aq soln of 2% 2,4-dinitro-1-naphthol-7-sulfonic acid sodium salt; "Naphthol Yellow S;" (EK 1393: M B356).

Test soln: Use the soln contg Group V* cations or make a given unknown soln alk with xs amm and $(NH_4)_2CO_3$ soln, heat to boiling and filter. Neutralize the filtrate with AcOH.

Procedure: To 10 ml of neutral test soln add 3 ml of reag soln and mix well. A yellow ppt forms if K^+ is present.

Sensitivity: 1 part K^+ in 2500 parts of soln.

Interferences: Rb, Ca, Sr, Ba, Cu, Ag, Pb, and Tl^+ intfr but are removed in the procedure above. Li, Na, Cs, NH_4^+, Mg, Zn, Cd, Hg, Al, Sn^{++}, As, Sb, Bi, Cr, Mn, Fe, Co, and Ni do not intfr.

References: Welcher, Vol. IV, p 19; C. A., **30**, 4115 (1936).

RUBIDIUM

Reagent: See reag for Cesium.

Procedure: Same as given for Cesium.

Sensitivity: 3 mg Rb per ml of soln.

Interferences: Cu, Ag, Cs, Hg, Tl^+, Sn, and Pb intfr but of these all except Cs are removed in the separations of Groups I–IV*. Cs may be removed by the procedure of Noyes and Bray, p 250–251.

Reference: Welcher, Vol. IV, p 20.

RUTHENIUM

Reagent: A soln of 0.2% dithiooxamide; "Rubeanic acid;" (EK 4394) in glacial AcOH.

* See Outline for Qualitative Analysis.

Test soln: Make unknown soln acid to litmus with HCl.

Procedure: To 5 ml of test soln add 1–2 drops of reag soln. If a ppt forms, continue to add reag soln dropwise until no more ppt forms. Filter and warm filtrate gently. A blue color forms if Ru is present.

Sensitivity: 1 part Ru in 250,000 parts of soln.

Interferences: Pd and Pt form red ppts which are removed in procedure above. Os does not intfr.

References: Welcher, Vol. IV, p 154; C. A., **28**, 4679 (1934).

SCANDIUM

Follow procedure described under Indium.

SELENIUM

Reagent: An aq soln of 5% thiourea (EK 497; M CB798).

Test soln: Make unknown soln acid to litmus with conc HCl.

Procedure: To 5 ml of test soln add 5 drops reag soln, and boil. Allow to cool for 5 min. An orange-red ppt forms if Se is present.

Sensitivity: 5 ppm Se as selenite ion.

Interferences: Cu intfr. Nitrates intfr but extraction with ethyl acetate or diethyl ether removes this intfr. See also under Tellurium.

References: Welcher, Vol. IV, p 186; C. A., **32**, 1604 (1938).

SILICON, SILICATE

Reagent: (*a*) A soln of 0.25% benzidine (EK 33; M CB211) in 10% AcOH. (*b*) Dissolve 5 g of ammonium molybdate in 100 ml of cold H_2O and 35 ml of 6.6 *N* HNO_3.

Test soln: Make unknown soln acid to litmus with dil HNO_3.

Procedure: Add 2 drops of reag soln *b* to 1 ml of test soln. The acidity should not be greater than 0.5 *N*. Heat the mixture to boiling and cool. Then add 2 drops of reag soln *a* and 2 drops of a satd aq soln of AcONa. A blue color or a blue ppt forms if Si is present.

Sensitivity: About 1 part in 50,000 parts of soln.

Interferences: Phosphates and arsenates intfr and must be removed.

References: Welcher, Vol. II, p 296; C. A., **36**, 6943 (1942).

SILVER

Reagent: A satd soln of 5-(*p*-dimethylaminobenzylidene)rhodanine (EK 2748; M 4203) in acetone.

Test soln: Make the unknown soln sl acid with dil HNO_3.

Procedure: Place a drop of test soln on a spot plate, add 1 drop of 5% aq soln of KCN, then add 1 drop reag soln. A red-violet color appears if Ag is present.

Sensitivity: 0.63 mcg Ag^+ per ml of soln.

Interferences: Au, Pt, and Pd intfr. Hg^{++} does not intfr.

Reference: Welcher, Vol. III, p 419.

SODIUM

Reagent: Dissolve 0.1 g KOH and 0.05 g of 6,8-dichloro-2,4-(1H,3H)quinazolinedione; "6,8-Dichlorobenzoyleneurea;" "Sheibley's reagent;" (EK 4842) in 10 ml of water, warm and then cool.

Test soln: An aq soln of Group V* cations is evapd to dryness in a porcelain dish and heated until all amm salts are volatilized. Dissolve the residue in the least amount of water necessary.

* See Outline for Qualitative Analysis.

Procedure: Mix equal volumes of test soln and reag soln and let stand until a white ppt forms or until 4 hrs have elapsed. A white crystalline ppt forms if Na^+ is present.

Sensitivity: A ppt forms rapidly if more than 0.2 *M* NaCl is present; at 0.05 *N* 4 hrs are required for pptn.

Interferences: NH_4Cl intfr. Li, K, Rb, and Cs do not intfr.

References: *J. Org. Chem.*, **3**, 414 (1938); C. A., **33**, 2895 (1939).

STRONTIUM

Reagent: An aq soln of 5% sodium rhodizonate (M 5302).

Test soln: Take 2 ml of the AcOH soln from Group IV* which, after removal of the pptd $BaCrO_4$, might contain $SrCrO_4$ and $CaCrO_4$.

Procedure: Moisten filter paper with test soln. Add 1 drop reag soln to the filter paper. A red-brown spot shows the presence of Ba^{++} or Sr^{++}. This spot remains when treated with a drop of 1 *N* HCl if Sr^{++} is present.

Sensitivity: 4 mcg of Sr per ml of soln.

Interferences: Ba^{++} intfr but Ca^{++} does not.

References: Welcher, Vol. I, p 221; C. A., **34**, 4685 (1940).

SULFATE

Reagent: An aq soln of 5% sodium or potassium rhodizonate (EK 2942; M 5302).

Test soln: Take the aq "prepared soln" for acidic constituents* and neutralize it with dil HCl.

Procedure: Place a drop of 1% aq $BaCl_2$ soln on filter paper and then 1 drop of reag soln. A red spot forms. Add 1–2 drops of test soln to the red spot. If SO_4^{2-} is present the red spot will disappear.

Sensitivity: Reported only as very sensitive.

Interferences: Chromates intfr. Heavy metals intfr but these are not present when the "prepared soln" is used as a test soln.

Reference: Welcher, Vol. I, p 222.

SULFITE

Reagent: Dissolve 0.34 g fuchsin (EK 1762; M B300) in 1 liter H_2O contg 1 g H_2SO_4. Warm this mixture and then cool.

Test soln: Prepare a satd aq soln of the material to be tested and add 15 volumes of H_2O, or use the original unknown soln.

Procedure: To 10 ml of test soln add a drop of phenolphthalein indicator soln. If the resulting soln is pink, add 0.1 *N* AcOH until colorless. Add 3–5 drops reag soln. The pink color of the reag is bleached within a few minutes if sulfite is present.

Sensitivity: 0.06 mg SO_2 per liter of soln.

Interferences: Mono and polysulfides intfr and must be removed with $CdCl_2$. Thiosulfate, thionate, bicarbonate, and phosphates do not intfr.

References: Welcher, Vol. IV, p 500; C. A., **25**, 2076 (1931).

SULFUR

Reagent: Pyridine (EK 274; M CB656) which is water-clear.

Test soln: If the unknown is in soln, evap to dryness on the water bath and extract the residue with hot reag. Filter, if necessary, and use filtrate.

* See Outline for Qualitative Analysis.

Procedure: To the filtrate above, add one-tenth its volume of 2 *N* NaOH soln or of satd aq $NaHCO_3$ soln. Compare the color of this soln with those in the table below:

Concn of S in pyridine	With NaOH	With $NaHCO_3$
1:100	Deep red-brown	Deep green-blue
1:1000	Dark olive-green	Dark blue
1:10,000	Greenish-blue	Strong blue
1:100,000	Light sky-blue	Sky blue
1:300,000	Trace of blue	Very light blue

Interferences: Hydrocarbons and CS_2 inhibit color formation. Polyhalogenated hydrocarbons, $CHCl_3$, Cl_2, Br_2 and I_2 intfr.

References: Welcher, Vol. III, p 39; C. A., **34**, 4099 (1938).

SULFIDE

Reagent: *p*-Aminodimethylaniline sulfate (EK 1333; M 1153).

Test soln: An aq soln of the unknown.

Procedure: Mix 5 ml of test soln with 0.1 ml of conc HCl and then add a small crystal of the reag. When the crystal has dissolved, add 1–2 drops of 0.1 *N* $FeCl_3$ soln. A blue color forms if H_2S is present.

Sensitivity: 0.01 mg H_2S per liter of soln.

Interferences: Organic matter, alkalies, NO_2^-, and NO_3^- intfr but are easily removed; see C. A., **36**, 5110 (1942).

Reference: Welcher, Vol. II, p 252.

TANTALUM

Follow procedure described under Niobium.

TARTRATE

Reagent: Dissolve 2 g of resorcinol (EK 222; M 2869) and 10 g of KBr in 100 ml of H_2O. After the solid has dissolved, add 1 ml of conc H_2SO_4.

Test soln: Neutralize 5 ml of "prepared soln" for acidic constituents* with dil H_2SO_4. Add 0.1 g Zn and 5 drops of aq $CuSO_4$ soln. Filter and use filtrate for test.

Procedure: Mix 0.1 ml of reag soln with 2 ml of conc H_2SO_4 and then add 0.1 ml of test soln. Heat gently. A blue color forms if tartrate is present. After neutralizing with NaOH, the color changes to bright red.

Sensitivity: Not extremely sensitive; detc 20 mg per ml.

Interference: Only chloral intfr. ClO^-, ClO_3^-, NO_3^-, and MnO_4^- are removed by reduction with Zn-Cu couple in the procedure above.

Reference: C. A., **30**, 1327 (1936).

TELLURIUM

When the test for Selenium is performed and if Te is present, this procedure will produce a yellow color in dilute soln instead of a red ppt. If the soln is concentrated and if Te is present, a yellow ppt will form which is insoluble in H_2O but soluble in EtOH. By diluting the soln to prevent the formation of the yellow ppt, Te can be detected in the presence of Se.

* See Outline for Qualitative Analysis.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

THALLIUM

Reagent: A soln of 10% α-mercapto-*N*-2-naphthylacetamide; "Thioglycolic-β-aminonaphthalide;" "Thionalide;" (EK 5828) in acetone.

Test soln: Neutralize the aq soln of unknown with 2 *N* NaOH soln.

Procedure: To 10 ml of test soln add 2 g sodium tartrate and 4 g KCN. Then add 10 ml of 2 *N* NaOH and dilute with H_2O to 100 ml total volume. Add 25 ml reag soln, heat to boiling and then cool. A lemon yellow ppt forms if Tl^+ is present.

Sensitivity: 0.1 ppm Tl.

Interferences: None reported with this procedure.

References: Welcher, Vol. IV, p 173; C. A., 31, 6998 (1937).

THORIUM

Reagent: Saturate 10 ml of EtOH with alizarin (EK T1014) and then add dil HCl dropwise until a pure yellow color is obtained. Add an equal volume of EtOH and filter. Use filtrate.

Test soln: To the ppt from Group III* containing the $Al(OH)_3$ group, add HCl until dissolved. To 2 ml of this soln, add 1 ml of a satd aq soln of $(NH_4)_2C_2O_4$. Filter and discard filtrate. Add 3 ml of a satd aq soln of $(NH_4)_2C_2O_4$, heat to boiling, and filter. To cool filtrate, add sl xs of 6 *N* HCl, mix well and filter. To the ppt of $Th(C_2O_4)_2$ add 5 ml of 3 *N* $AcONH_4$ soln and boil. Use this soln for test.

Procedure: To 1 drop of test soln, add 1 drop reag soln. Heat to boiling and allow to cool. A red to violet color forms. Now add 1 drop of dil HCl. A red color persists if Th is present.

Sensitivity: 10 mg Th per ml of soln.

Interferences: Be, Al, Ti, and Zr intfr but the procedure above removes intf.

Reference: Welcher, Vol. I, p 387.

TIN

Reagent: A satd aq soln of cacotheline (EK 4396; M 1276).

Test soln: To 10 ml of the aq soln from Group II* contg $AsCl_3$, $SbCl_3$ or $SnCl_2$ in HCl soln, add 0.5 g tartaric acid. After the tartaric acid has dissolved, saturate the soln with H_2S gas and filter. Boil the filtrate to remove H_2S and use this soln for test.

Procedure: Moisten a piece of filter paper with reag soln and before it dries add 1 drop of test soln. A red ring on yellow paper forms if Sn is present.

Sensitivity: 1 part Sn in 250,000 parts of soln.

Interferences: Sb intfr but is removed by the procedure above. Sulfites and thiosulfates intfr but they are also removed by the procedure above.

References: Welcher, Vol. IV, p 218; C. A., 34, 4685 (1940).

TITANIUM

Reagent: Dissolve 5 g of thymol (EK 248; M 2510) in 5 ml of 3 *N* AcOH and add 95 ml of conc H_2SO_4. Protect this soln from sunlight.

Test soln: Dissolve a sample containing 1–10 mg of TiO_2 in conc H_2SO_4 or, if necessary, fuse a solid sample with $KHSO_4$ and dissolve the fused mass in conc H_2SO_4.

Procedure: To 5 ml of test soln add 5 ml of reag soln. A red to reddish-yellow color forms if Ti^{4+} is present.

Sensitivity: 0.1 mg TiO_2 per ml of soln.

Interferences: H_2F_2, F^-, and WO_4^{2-} intfr. Phosphates, Cl^-, and Sn do not intfr.

References: Welcher, Vol. I, p 186; C. A., 6, 3246 (1912).

* See Outline for Qualitative Analysis.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

TUNGSTEN

Reagent: A soln of 5 mg malachite green (M B330) in 100 ml H_2O.
Test soln: Make an aq soln of the unknown just acid to litmus with HCl.
Procedure: To 0.5 ml of test soln in a small test tube, add 0.1 ml of aq 1% titanous chloride soln and 0.1 ml of reag soln. The color fades out in 3 seconds if as much as 1 part W per 100,000 parts of soln is present. Run a blank test using 0.5 ml of distilled water instead of test soln. It will require 4–5 min for the color to fade from the blank test.
Sensitivity: 1 part W in 500,000 parts of soln.
Interferences: Mo and cations easily reduced intfr. F^- and NO_3^- must be absent.
References: Welcher, Vol. IV, p 575; C. A., 33, 79 (1939).

URANIUM

Reagent: An aq soln of 5% 1-allyl-2-thiourea; "Thiosinamine;" (EK 12; M 5109).
Test soln: An aq soln of unknown.
Procedure: To 4 ml of reag soln, add 0.2 ml of 30% NaOH soln and 3 drops of test soln. Heat to boiling and cool. A yellow ppt forms if UO_2^{++} is present.
Sensitivity: Reported to be very sensitive.
Interferences: Only Cd intfr and Cd^{++} may be removed as CdS by pptn with H_2S from sl acid soln before making test.
References: Welcher, Vol. IV, p 109; C. A., 3, 524 (1909).

VANADIUM

Reagent: A satd aq soln of cacotheline (EK 4396; M 1276).
Test soln: Remove ions of Groups I and II* by means of HCl and pptn with H_2S in acid soln, boil filtrate to remove H_2S and use for test.
Procedure: On a spot plate mix 1 drop of test soln, 0.05 g Zn powder, and 1 drop of reag soln. A violet to red color forms if V is present.
Sensitivity: 1 part V in 25,000 parts of soln.
Interferences: Sn intfr but is removed by the procedure above. MoO_4^{2-} and WO_4^{2-} intfr but may be removed by the procedure of Noyes and Bray, p 170.
References: Welcher, Vol. IV, p 219; Feigl, p 69.

ZIRCONIUM

Reagent: Saturate 10 ml of EtOH with alizarin (EK T1014) and then add dil HCl dropwise until a pure yellow color is obtained. Add an equal volume of EtOH and filter. Use filtrate.
Test soln: Neutralize the aq unknown soln with HCl or NaOH as conditions require.
Procedure: To 1 drop of test soln, add 1 drop reag soln. Heat to boiling and allow to cool. A red to violet color forms. Now add 1 drop of dil HCl. A red color persists if Zr is present.
Sensitivity: 1 ppm of Zr.
Interferences: Be, Al, Ti, and Th give a red color but this fades with HCl. F^-, SO_4^{2-}, PO_4^{3-}, MoO_4^{2-}, and WO_4^{2-} intfr.
References: Welcher, Vol. IV, p 417.

ZINC

Reagent: (*a*) Dissolve 25 ml of mono-free diethylaniline (EK 93; M 2208) in 200 ml of cold 9 *M* H_2SO_4. (*b*) An aq soln of 2% $K_4Fe(CN)_6$.

* See Outline for Qualitative Analysis.

ORGANIC REAGENTS FOR INORGANIC ANALYSIS

Test soln: Use the soln in Group III* which may contain $NaAlO_2$, Na_2CrO_4, or Na_2ZnO_2 and make it just acid with 6 *N* H_2SO_4.

Procedure: Mix 0.75 ml of reag soln *b* with 0.5 ml of reag soln *a*, then add 1–2 drops of test soln. The color changes from orange to reddish-brown and the soln becomes turbid if as much as 0.01 mg Zn is present. With a high concentration of Zn, a ppt forms.

Sensitivity: 0.01 mg Zn per ml of soln.

Interferences: Co, Ni, Mn, and Cu intfr but are removed by the procedure above. Al^{3+} and CrO_4^{2-} do not intfr.

References: Welcher, Vol. II, p 347–8; C. A., **27**, 2902 (1933).

* See Outline for Qualitative Analysis.

CONCENTRATIONS OF LABORATORY REAGENTS

COMMONLY USED ACIDS AND AMMONIUM HYDROXIDE*

Freshly opened bottles of these reagents are uniformly of the concentrations indicated below. This may not be true of bottles long opened and this is especially true of ammonia which rapidly loses its strength. In preparing volumetric solutions, it is well to be on the safe side and take a little more than the calculated volume of the concentrated reagent, since it is much easier to dilute a concentrated solution than to strengthen one that is too weak. The *5N* solutions present obvious advantages over the usual indefinite dilutions for use as shelf reagents; however, it is not necessary that these shelf reagents be highly accurate.

	HCl	HNO_3	H_2SO_4	NH_4OH	$HC_2H_3O_2$
Mol. wt.	36.46	63.02	98.08	35.04	60.03
Average sp. gr. of conc. reagent	1.19	1.42	1.84	0.90	1.06
Average % present in conc. reagent	36.0	69.5	96.0	58.6	99.5
Grams active ingredient per ml.	0.426	0.985	1.76	0.527	1.055
Normality of conc. reagent	11.7	15.6	35.9	15.1	17.6
Ml. conc. reagent/liter *N* solution	85.5	64.0	27.9	66.5	56.9
Ml. to dilute to 500 cc. for use as shelf reagent (*5N*)	214	160	70	166	143

Routine Normal Solutions †

A concentrated C. P. acid usually comes to the laboratory in a bottle having a label which states: its molecular weight, M; its specific gravity, d; and its percentage assay, p. When such an acid is used in preparing an aqueous solution of desired normality, N, a convenient formula to employ is:

$$V \quad \frac{100\,MN}{bpd}$$

wherein b is the basicity of the acid and V is the number of milliliters of concentrated acid required for one liter of the dilute solution.

Example.—Acid Sulfuric is dibasic and has the molecular weight 98.08. If the concentrated acid assays 95.5% and has the specific gravity 1.84, the volume required for one liter of a 0.2 normal solution is:

$$\frac{100 \times 98.08 \times 0.2}{2 \times 95.5 \times 1.84} = 5.58 \text{ ml.}$$

Such a solution may often be used just as it stands. Where accuracy is required, it is most conveniently standardized by comparison with a high grade Potassium Biphthalate or other primary standard, *q.v.*

LABORATORY SOLUTIONS

General Reagents, Indicators and Special Solutions

Unless otherwise stated, the term *g per liter* signifies grams of the formula indicated dissolved in water and made up to a liter of solution. See also *Standard Titrimetric Solutions*.

Acetic acid, $HC_2H_3O_2$—*6N*: 350 ml glacial acetic acid per liter.

Alcohol, amyl, $C_5H_{11}OH$: use as purchased.

Alcohol, ethyl, C_2H_5OH; 95% alcohol, as purchased.

Alizarin, dihydroxyanthraquinone (indicator): dissolve 0.1 g in 100 ml alcohol; pH range yellow 5.5—6.8 red.

Alizarin yellow R, sodium *p*-nitrobenzeneazosalicylate (indicator): dissolve 0.1 g in 100 ml water; pH range yellow 10.1—violet 12.1.

Alizarin yellow GG, salicyl yellow, sodium *m*-nitrobenzeneazosalicylate (indicator); dissolve 0.1 g in 100 ml 50% alcohol; pH range yellow 10.0—12.0 lilac.

Alizarin S, alizarin carmine, sodium alizarin sulfonate (indicator): dissolve 0.1 g in 100 ml water; pH range yellow 3.7—5.2 violet.

Aluminon (qualitative test for aluminum). The reagent consists of 0.1% solution of the ammonium salt of aurin tricarboxylic acid. A bright red precipitate, persisting in alkaline solution, indicates aluminum. See special table: *Organic Reagents for Inorganic Analysis*.

Aluminum chloride, $AlCl_3$—*0.5N*: 22 g per liter.

Aluminum nitrate, $Al(NO_3)_3 \cdot 7.5H_2O$—*0.5N*: 58 g per liter.

Aluminum sulfate, $Al_2(SO_4)_3 \cdot 18H_2O$—*0.5N*: 55 g per liter.

Ammonium acetate, $NH_4C_2H_3O_2$—*3N*: 231 g per liter.

Ammonium carbonate, $(NH_4)_2CO_3 \cdot H_2O$—*3N*: 171 g per liter; for the anhydrous salt: 144 g per liter.

Ammonium chloride, NH_4Cl—*3N*: 161 g per liter.

Ammonium hydroxide, NH_4OH—*15N*: the concentrated solution which contains 28% NH_3; for *6N*: 400 ml per liter.

Ammonium molybdate, $(NH_4)_2MoO_4$—*N*: dissolve 88.3 g of solid $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ in 100 ml *6N* NH_4OH. Add 240 g of solid NH_4NO_3 and dilute to one liter. Another method is to take 72 g of MoO_3, and 130 ml of water and 75 ml of *15N* NH_4OH; stir mechanically until nearly all has dissolved, then add it to a solution of 240 ml concentrated HNO_3 and 500 ml of water; stir continuously while solutions are being mixed; allow to stand 3 days, filter, and use the clear filtrate.

Ammonium nitrate, NH_4NO_3—*N*: 80 g per liter.

Ammonium oxalate, $(NH_4)_2C_2O_4 \cdot H_2O$—*0.5N*: 40 g per liter.

Ammonium polysulfide (yellow ammonium sulfide), $(NH_4)_2S_x$: allow the colorless $(NH_4)_2S$ to stand, or add sulfur.

Ammonium sulfate, $(NH_4)_2SO_4$—*0.5 N*: 33 g per liter; saturated: dissolve 780 g of $(NH_4)_2SO_4$ in water and make up to a liter.

Ammonium sulfide (colorless), $(NH_4)_2S$—saturated: pass H_2S through 200 ml of concentrated NH_4OH in the cold until no more gas is dissolved, add 200 ml NH_4OH and dilute with water to a liter; the addition of 15 g of sulfur is sufficient to make the polysulfide.

Ammonium thiocyanate: see *Titrimetric Solutions*.

Antimony pentachloride, $SbCl_5$—*0.5N*: 30 g per liter.

Antimony trichloride, $SbCl_3$—*0.5N*: 38 g per liter.

Aqua regia: mix 3 parts of concentrated HCl and 1 part of concentrated HNO_3 just before ready to use.

Arsenic acid, $H_3AsO_4 \cdot 0.5H_2O$—*0.5N* ($=\frac{1}{2}H_3AsO_4 \div 5$): 15 g per liter.

Arsenous oxide, As_2O_3—*0.25N*: 8 g per liter for saturation. See also *Titrimetric Solutions*.

LABORATORY SOLUTIONS

Aurichloric acid, $HAuCl_4 \cdot 3H_2O$: dissolve in ten parts of water.

Aurin, see *rosolic acid.*

Azolitmin solution (indicator): make up a 1% solution of azolitmin by boiling in water for 5 minutes; it may be necessary to add a small amount of NaOH to make the solution neutral; pH range red 4.5—8.3 blue.

Bang's reagent (for glucose estimation): dissolve 100 g of K_2CO_3, 66 g of KCl, and 160 g of $KHCO_3$ in the order given in about 700 ml of water at 30°C. Add 4.4 g of copper sulfate and dilute to 1 liter after the CO_2 is evolved. This solution should be shaken only in such a manner as not to allow the entry of air. After 24 hours 300 ml are diluted to a liter with saturated KCl solution, shaken gently and used after 24 hours; 50 ml ≈ 10 mg glucose.

Barfoed's reagent (test for glucose): dissolve 66 g of cupric acetate and 10 ml of glacial acetic acid in water and dilute to one liter.

Barium and Calcium chlorides: see *precipitating reagent.*

Barium chloride, $BaCl_2 \cdot 2H_2O$—0.5*N*: 61 g per liter.

Barium hydroxide, $Ba(OH)_2 \cdot 8H_2O$—0.2*N*: 32 g per liter for saturation.

Barium nitrate, $Ba(NO_3)_2$—0.5*N*: 65 g per liter.

Baudisch's reagent: see *cupferron.*

Benedict's qualitative reagent (for glucose): dissolve 173 g of sodium citrate and 100 g of anhydrous sodium carbonate in about 600 ml of water, and dilute to 850 ml; dissolve 17.3 g of $CuSO_4 \cdot 5H_2O$ in 100 ml of water and dilute to 150 ml; this solution is added to the citrate-carbonate solution with constant stirring. See also the quantitative reagent below.

Benedict's quantitative reagent (sugar in urine): This solution contains 18 g copper sulfate, 100 g of anhydrous sodium carbonate, 200 g of potassium citrate, 125 g of potassium thiocyanate, and 0.25 g of potassium ferrocyanide per liter; 1 ml of this solution ≈ 0.002 sugar.

Benzidine hydrochloride solution (for sulfate determination): mix 6.7 g of benzidine $[C_{12}H_8(NH_2)_2]$ or 8.0 g of the hydrochloride $[C_{12}H_8(NH_2)_2 \cdot 2HCl]$ into a paste with 20 ml of water; add 20 ml of HCl (sp. gr. 1.12) and dilute the mixture to one liter with water; each ml of this solution is equivalent to 0.00357 g H_2SO_4.

Benzopurpurine 4B (indicator): dissolve 0.1 g in 100 ml water; pH range blue-violet 1.3—4.0 red.

Benzoyl auramine (indicator): dissolve 0.25 g in 100 ml methyl alcohol; pH range violet 5.0—5.6 pale yellow. Since this compound is not stable in aqueous solution, hydrolyzing slowly in neutral medium, more rapidly in alkaline and still more rapidly in acid solution, the indicator should not be added until one is ready to titrate. The acid quinoid form of the compound is dichroic, showing a red-violet in thick layers and blue in thin. At a pH of 5.4 the indicator appears a neutral gray color by daylight or a pale red under tungsten light. The change to yellow is easily recognized in either case. Cf. Scanlan and Reid, *Ind. Eng. Chem., Anal. Ed.* 7, 125 (1935).

Bertrand's reagents (glucose estimation): (*a*) 40 g of copper sulfate diluted to one liter; (*b*) rochelle salt 200 g, NaOH 150 g and sufficient water to make one liter; (*c*) ferric sulfate 50 g, H_2SO_4 200 g and sufficient water to make one liter; (*d*) $KMnO_4$ 5 g and sufficient water to make one liter.

Bial's reagent (for pentoses): dissolve 1 g of orcinol in 500 ml of 30% HCl to which 30 drops of a 10% ferric chloride solution have been added.

Bismuth chloride, $BiCl_3$—0.5*N*: 52 g per liter, using 1:5 HCl in place of water.

Bismuth nitrate, $Bi(NO_3)_3 \cdot 5H_2O$—0.25*N*: 40 g per liter, using 1:5 HNO_3 in place of water.

Bismuth standard solution (quantitative color test for Bi): dissolve 1 g of bismuth in a mixture of 3 ml of concentrated HNO_3 and 2.8 ml of H_2O and make up to 100 ml with glycerol. Also dissolve 5 g of KI in 5 ml of water and make up to 100 ml with glycerol. The

two solutions are used together in the colorimetric estimation of Bi.

Boutron-Boudet solution: see *soap solution.*

Bromchlorophenol blue, dibromodichlorophenol-sulfonphthalein (indicator): dissolve 0.1 *g* in 8.6 ml 0.02 *N* NaOH and dilute with water to 250 ml; pH range yellow 3.2—4.8 blue.

Bromcresol green, tetrabromo-*m*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 7.15 ml 0.02 *N* NaOH and dilute with water to 250 ml; or, 0.1 g in 100 ml 20% alcohol; pH range yellow 4.0—5.6 blue.

Bromcresol purple, dibromo-*o*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 9.5 ml 0.02 *N* NaOH and dilute with water to 250 ml; or, 0.1 g in 100 ml 20% alcohol; pH range yellow 5.2—6.8 purple.

Bromine water, saturated solution: to 400 ml water add 20 ml of bromine; use a glass stopper coated with petrolatum.

Bromphenol blue, tetrabromophenol-sulfonphthalein (indicator): dissolve 0.1 g in 7.45 ml 0.02 *N* NaOH and dilute with water to 250 ml; or, 0.1 g in 100 ml 20% alcohol; pH range yellow 3.6—4.6 violet-blue.

Bromphenol red, dibromophenol-sulfonphthalein (indicator): dissolve 0.1 g in 9.75 ml 0.02 *N* NaOH and dilute with water to 250 ml; pH range yellow 5.2—7.0 red.

Bromthymol blue, dibromothymol-sulfonphthalein (indicator): dissolve 0.1 g in 8.0 ml 0.02 *N* NaOH and dilute with water to 250 ml; or, 0.1 g in 100 ml of 20% alcohol; pH range yellow 6.0—7.6 blue.

Brucke's reagent (protein precipitant): dissolve 50 g of KI in 500 ml of water, saturate with HgI_2 (about 120 g), and dilute to one liter.

Cadmium chloride, $CdCl_2$—0.5*N*: 46 g per liter.

Cadmium nitrate, $Cd(NO_3)_2\,4H_2O$—0.5*N*: 77 g per liter.

Cadmium sulfate, $CdSO_4{\cdot}4H_2O$—0.5*N*: 70 g per liter.

Calcium chloride, $CaCl_2{\cdot}6H_2O$—0.5*N*: 55 g per liter.

Calcium hydroxide, $Ca(OH)_2$—0.04*N*: 10 g per liter for saturation.

Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$—0.5*N*: 59 g per liter.

Calcium sulfate, $CaSO_4{\cdot}2H_2O$—0.03*N*: mechanically stir 10 *g* in a liter of water for 3 hours; decant and use the clear liquid.

Carbon disulfide, CS_2: commercial grade which is colorless.

Chloride reagent: dissolve 1.7 *g* of $AgNO_3$ and 25 *g* KNO_3 in water, add 17 ml of concentrated NH_4OH and make up to one liter with water.

Chlorine water, saturated solution: pass chlorine gas into small amounts of water as needed; solutions deteriorate on standing.

Chloroform, $CHCl_3$: commercial grade.

Chloroplatinic acid, $H_2PtCl_6{\cdot}6H_2O$—10% solution: dissolve 1 *g* in 9 ml of water; keep in a dropping bottle.

Chlorphenol red, dichlorophenol-sulfonphthalein (indicator): dissolve 0.1 *g* in 11.8 ml 0.02 *N* NaOH and dilute with water to 250 ml; or, 0.1 *g* in 100 ml 20% alcohol; pH range yellow 5.2—6.6 red.

Chromic chloride, $CrCl_3$—0.5*N*: 26 g per liter.

Chromic nitrate, $Cr(NO_3)_3$—0.5*N*: 40 g per liter.

Chromic sulfate, $Cr_2(SO_4)_3{\cdot}18H_2O$—0.5*N*: 60 g per liter.

Cobaltous nitrate, $Co(NO_3)_2{\cdot}6H_2O$—0.5*N*: 73 g per liter.

Cobaltous sulfate, $CoSO_4{\cdot}7H_2O$—0.5*N*: 70 g per liter.

Cochineal (indicator): triturate 1 *g* with 75 ml alcohol and 75 ml water, let stand for two days and filter; pH range red 4.8—6.2 violet.

Congo red, sodium tetrazodiphenyl-naphthionate (indicator): dissolve 0.1 *g* in 100 ml water; pH range blue 3.0—5.2 red.

Corallin (indicator): see *rosolic acid.*

Cresol red, *o*-cresol-sulfonphthalein (indicator): dissolve 0.1 *g* in 13.1 ml 0.02 *N* NaOH and dilute with water to 250

LABORATORY SOLUTIONS

ml; or, 0.1 g in 100 ml 20% alcohol; pH range yellow 7.2—8.8 red.

o-Cresolphthalein (indicator): dissolve 0.1 g in 250 ml alcohol; pH range colorless 8.2—10.4 red.

Cupferron (iron analysis): dissolve 6 g of ammonium nitrosophenyl-hydroxylamine (cupferron) in water and dilute to 100 ml. This solution is stable for about one week if protected from light. See special table: *Organic Reagents for Inorganic Analysis.*

Cupric chloride, $CuCl_2 \cdot 2H_2O$—0.5*N*: 43 g per liter.

Cupric nitrate, $Cu(NO_3)_2 \cdot 6H_2O$—0.5*N*: 74 g per liter.

Cupric sulfate, $CuSO_4 \cdot 5H_2O$—0.5*N*: 62 g per liter.

Cuprous chloride, CuCl—0.5*N*: 50 g per liter, using 1:5 HCl in place of water.

Cuprous chloride, acid (for gas analysis, absorption of CO): cover the bottom of a two-liter bottle with a layer of copper oxide ⅜ inch deep, and place a bundle of copper wire an inch thick in the bottle so that it extends from the top to the bottom. Fill the bottle with HCl (sp. gr. 1.10). The bottle is shaken occasionally, and when the solution is colorless or nearly so, it is poured into half-liter bottles containing copper wire. The large bottle may be filled with hydrochloric acid, and by adding the oxide or wire when either is exhausted, a constant supply of the reagent is available.

Cuprous chloride, ammoniacal: this solution is used for the same purpose, and is made in the same manner as the acid cuprous chloride above, except that the acid solution is treated with ammonia until a faint odor of ammonia is perceptible. Copper wire should be kept with the solution as in the acid reagent.

Curcumin (indicator): prepare a saturated aqueous solution; pH range yellow 6.0—8.0 brownish red.

Dibromophenol-tetrabromophenol-sulfonphthalein (indicator): dissolve 0.1 g in 1.21 ml 0.1*N* NaOH and dilute with water to 250 ml; pH range yellow 5.6—7.2 purple.

Dimethyl glyoxime, $(CH_3CNOH)_2$—0.01*N*: 6 g in 500 ml of 95% alcohol. See special table: *Organic Reagents for Inorganic Analysis.*

2,4-Dinitrophenol (indicator): dissolve 0.1 g in a few ml alcohol, then dilute with water to 100 ml; pH range colorless 2.6—4.0 yellow.

2,5-Dinitrophenol (indicator): dissolve 0.1 g in 20 ml alcohol, then dilute with water to 100 ml; pH range colorless 4—5.8 yellow.

2,6-Dinitrophenol (indicator): dissolve 0.1 g in a few ml alcohol, then dilute with water to 100 ml; pH range colorless 2.4—4.0 yellow.

Esbach's reagent (estimation of proteins): dissolve 10 g of picric acid and 20 g of citric acid in water and dilute to one liter.

Eschka's Mixture (sulfur in coal): mix 2 parts of porous calcined MgO with 1 part of anhydrous Na_2CO_3; not a solution but a dry mixture.

Ether, $(C_2H_5)_2O$—use commercial grade.

***p*-Ethoxychrysoidine,** *p*-ethoxybenzeneazo-*m*-phenylenediamine (indicator): dissolve 0.1 g of the base in 100 ml 90% alcohol; or, 0.1 g of the hydrochloride salt in 100 ml water; pH range red 3.5—5.5 yellow.

Ethyl *bis*-(2,4-dinitrophenyl) acetate (indicator): the stock solution is prepared by saturating a solution containing equal volumes of alcohol and acetone with the indicator; pH range colorless 7.4—9.1 deep blue. This compound is available commercially. The preparation of this compound is described by Fehnel and Amstutz, *Ind. Eng. Chem., Anal. Ed.* **16**, 53 (1944), and by von Richter, *Ber.* **21**, 2470 (1888), who recommend it for the titration of orange- and red-colored solutions or dark oils in which the end-point of phenolphthalein is not easily visible. The indicator is an orange solid which after crystallization from benzene gives pale yellow crystals melting at 150–153.5°C, uncorrected.

Fehling's solution (sugar detection and estimation): (*a*) Copper sulfate solution: dissolve 34.639 g of $CuSO_4 \cdot$

$5H_2O$ in water and dilute to 500 ml. (*b*) Alkaline tartrate solution: dissolve 173 g of rochelle salts ($KNaC_4H_4O_6 \cdot 4H_2O$) and 125 g of KOH in water and dilute to 500 ml. Equal volumes of the two solutions are mixed just prior to use. The Methods of the Assoc. of Official Agricultural Chemists give 50 g of NaOH in place of the 125 g KOH.

Ferric chloride, $FeCl_3$—0.5*N*: 27 g per liter.

Ferric nitrate, $Fe(NO_3)_3 \cdot 9H_2O$—0.5*N*: 67 g per liter.

Ferrous ammonium sulfate, Mohr's salt, $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$—0.5*N*: 196 g per liter. See also *Titrimetric Solutions*.

Ferrous sulfate, $FeSO_4 \cdot 7H_2O$—0.5*N*: 80 g per liter; add a few drops of H_2SO_4.

Folin's mixture (for uric acid): dissolve 500 g of ammonium sulfate, 5 g of uranium acetate, and 6 ml of glacial acetic acid, in 650 ml of water. The volume is about a liter.

Formal or Formalin: use the commercial 40% solution of formaldehyde.

Froehde's reagent (gives characteristic colorations with certain alkaloids and glycosides): dissolve 0.01 g of sodium molybdate in 1 ml of concentrated H_2SO_4; use only a freshly prepared solution.

Gallein (indicator): dissolve 0.1 g in 100 ml alcohol; pH range light brown-yellow 3.8—6.6 rose.

Glyoxylic acid solution (protein detection): cover 10 g of magnesium powder with water, and add slowly 250 ml of a saturated oxalic acid solution, keeping the mixture cool; filter off the magnesium oxalate, acidify the filtrate with acetic acid and make up to a liter with water.

Guaiacum tincture: dissolve 1 g of guaiacum in 100 ml of alcohol.

Gunzberg's reagent (detection of HCl in gastric juice): dissolve 4 g of phloroglucinol and 2 g of vanillin in 100 ml of absolute alcohol; use only a freshly prepared solution.

Hager's reagent (for alkaloids): this reagent is a saturated solution of picric acid in water.

Hanus solution (for determination of iodine number): dissolve 13.2 g of iodine in a liter of glacial acetic acid that will not reduce chromic acid; add sufficient bromine to double the halogen content determined by titration (3 ml is about the right amount). The iodine may be dissolved with the aid of heat, but the solution must be cold when the bromine is added.

Hematoxylin (indicator): dissolve 0.5 g in 100 ml alcohol; pH range yellow 5.0—6.0.

Heptamethoxy red, 2,4,6,2′,4′,2″,4″-heptamethoxytriphenyl carbinol (indicator): dissolve 0.1 g in 100 ml alcohol; pH range red 5.0—7.0 colorless.

Hydriodic acid, HI—0.5*N*: 64 g per liter.

Hydrobromic acid, HBr—0.5*N*: 40 g per liter.

Hydrochloric acid, HCl—5*N*: 182 g per liter; sp. gr. 1.084. See also *Titrimetric Solutions*.

Hydrofluoric acid, H_2F_2—48% solution: use as purchased, and keep in the special container.

Hydrogen peroxide, H_2O_2—3% solution: use as purchased.

Hydrogen sulfide, H_2S: prepare a saturated aqueous solution.

Indicator solutions: a number of indicator solutions are listed in this section under the names of the indicators; *e.g.*, alizarin, aurin, azolitmin, *et al.* which follow alphabetically. See also various index entries.

Indigo carmine, sodium indigodisulfonate (indicator): dissolve 0.25 g in 100 ml 50% alcohol; pH range blue 11.6—14.0 yellow.

Indo-oxine, 5,8-quinolinequinone-8-hydroxy-5-quinoyl-5-imide (indicator): dissolve 0.05 g in 100 ml alcohol; pH range red 6.0—8.0 blue. Cf. Berg and Becker, *Z. anal. Chem.* 119, 81 (1940).

Iodeosin, tetraiodofluorescein (indicator): dissolve 0.1 g in 100 ml ether saturated with water; pH range yellow 0—about 4 rose-red; see also under *methyl orange*.

LABORATORY SOLUTIONS

Iodic acid, HIO_3—0.5*N* ($HIO_3/12$): 15 g per liter.

Iodine: see *tincture of iodine*; see also *Titrimetric Solutions.*

Lacmoid (indicator): dissolve 0.5 g in 100 ml alcohol; pH range red 4.4—6.2 blue.

Litmus (indicator): powder the litmus and make up a 2% solution in water by boiling for 5 minutes; pH range red 4.5—8.3 blue.

Lead acetate, $Pb(C_2H_3O_2)_2 \cdot 3H_2O$—0.5*N*: 95 g per liter.

Lead chloride, $PbCl_2$—saturated solution is 1/7*N*.

Lead nitrate, $Pb(NO_3)_2$—0.5*N*: 83 g per liter.

Lime water: see *calcium hydroxide.*

Magnesia mixture: 100 g of $MgSO_4$, 200 g of NH_4Cl, 400 ml of NH_4OH, 800 ml of water; each cc = 0.01 g phosphorus (P).

Magnesium chloride, $MgCl_2 \cdot 6H_2O$—0.5*N*: 50 g per liter.

Magnesium nitrate, $Mg(NO_3)_2 \cdot 6H_2O$—0.5*N*: 64 g per liter.

Magnesium sulfate, epsom salts, $MgSO_4 \cdot 7H_2O$—0.5*N*: 62 g per liter; saturated solution: dissolve 600 g of the salt in water and dilute to one liter.

Manganous chloride, $MnCl_2 \cdot 4H_2O$—0.5*N*: 50 g per liter.

Manganous nitrate, $Mn(NO_3)_2 \cdot 6H_2O$—0.5*N*: 72 g per liter.

Manganous sulfate, $MnSO_4 \cdot 7H_2O$—0.5*N*: 69 g per liter.

Marme's reagent (gives yellowish-white precipitate with salts of alkaloids): saturate a boiling solution of 4 parts of KI in 12 parts of water with CdI_2; then add an equal volume of cold saturated KI solution.

Marquis reagent (gives a purple-red coloration, then violet, then blue with morphine, codeine, dionine, and heroine): mix 3 ml of concentrated H_2SO_4 with 3 drops of a 35% formaldehyde solution.

Mayer's reagent (gives white precipitate with most alkaloids in a slightly acid solution): dissolve 13.55 g of $HgCl_2$ and 50 g of KI in a liter of water.

Mercuric chloride, $HgCl_2$—0.5*N*: 68 g per liter.

Mercuric nitrate, $Hg(NO_3)_2$—0.5*N*: 81 g per liter.

Mercuric sulfate, $HgSO_4$—0.5*N*: 74 g per liter.

Mercurous nitrate, $HgNO_3$: mix 1 part of $HgNO_3$, 20 parts of H_2O, and 1 part of HNO_3.

Metacresol purple, *m*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 13.6 ml 0.02*N* NaOH and dilute with water to 250 ml; acid pH range red 0.5—2.5 yellow, alkaline pH range yellow 7.4—9.0 purple.

Metanil yellow, diphenylaminoazo-*m*-benzene sulfonic acid (indicator): dissolve 0.25 g in 100 ml alcohol; pH range red 1.2—2.3 yellow.

Methyl green, hexamethylpararosaniline hydroxymethylate (component of mixed indicator): dissolve 0.1 g in 100 ml alcohol; when used with equal part of hexamethoxytriphenyl carbinol gives color change from violet to green at a titration exponent (pI) of 4.0.

Methyl orange, orange III, tropeolin D, sodium *p*-dimethylaminoazobenzene-sulfonate (indicator): dissolve 0.1 g in 100 ml water; pH range red 3.0—4.4 orange-yellow. If during a titration where methyl yellow is being used a precipitate forms which tends to remove the indicator from the aqueous phase, methyl orange will be found to be a more suitable indicator. This occurs, for example, in titrations of soaps with acids. The fatty acids, liberated by the titration, extract the methyl yellow so that the end-point cannot be perceived. Likewise methyl orange is more suitable for titrations in the presence of immiscible organic solvents such as carbon tetrachloride or ether used in the extraction of alkaloids for analysis. Iodeosin (*q.v.*) has also been proposed as an indicator for such cases. Cf. Mylius and Foerster, *Ber.* **24,** 1482 (1891); *Z. anal. Chem.* **31,** 240 (1892).

LABORATORY SOLUTIONS

Methyl red, *p*-dimethylaminoazobenzene-*o'*-carboxylic acid (indicator): dissolve 0.1 g in 18.6 ml 0.02 *N* NaOH and dilute with water to 250 ml; or, 0.1 g in 60% alcohol; pH range red 4.4—6.2 yellow.

Methyl violet (indicator): dissolve 0.25 g in 100 ml water; pH range blue 1.5—3.2 violet.

Methyl yellow, *p*-dimethylaminoazobenzene, benzeneazodimethylaniline (indicator): dissolve 0.1 g in 200 ml alcohol; pH range red 2.9—4.0 yellow. The color change from yellow to orange can be perceived somewhat more sharply than the change of methyl orange from orange to rose, so that methyl yellow seems to deserve preference in many cases. Cf. also under *methyl orange.*

Methylene blue, *N,N,N',N'*-tetramethylthionine (component of mixed indicator): dissolve 0.1 g in 100 ml alcohol; when used with equal part of methyl yellow gives color change from blue-violet to green at a titration exponent (pI) of 3.25; when used with equal part of 0.2% methyl red in alcohol gives color change from red-violet to green at a titration exponent (pI) of 5.4; when used with an equal part of neutral red gives color change from violet-blue to green at a titration exponent (pI) of 7.0.

Millon's reagent (gives a red precipitate with certain proteins and with various phenols): dissolve 1 part of mercury in 1 part of HNO_3 (sp. gr. 1.40) with gentle heating, then add 2 parts of water; a few crystals of KNO_3 help to maintain the strength of the reagent.

Mohr's salt: see *ferrous ammonium sulfate.*

α-Naphthol solution: dissolve 144 g of α-naphthol in enough alcohol to make a liter of solution.

α-Naphtholbenzein (indicator): dissolve 0.1 g in 100 ml 70% alcohol; pH range colorless 9.0—11.0 blue.

α-Naphtholphthalein (indicator): dissolve 0.1 g in 50 ml alcohol and dilute with water to 100 ml; pH range pale yellow-red 7.3—8.7 green.

Nessler's reagent (for free ammonia): dissolve 50 g of KI in the least possible amount of cold water; add a saturated solution of $HgCl_2$ until a very slight excess is indicated; add 400 ml of a 50% solution of KOH; allow to settle, make up to a liter with water, and decant.

Neutral red, toluylene red, dimethyldiaminophenazine chloride, aminodimethylaminotoluphenazine hydrochloride (indicator): dissolve 0.1 g in 60 ml alcohol and dilute with water to 100 ml; pH range red 6.8—8.0 yellow-orange.

Nickel chloride, $NiCl_2 \cdot 6H_2O$—0.5*N*: 59 g per liter.

Nickel nitrate, $Ni(NO_3)_2 \cdot 6H_2O$—0.5 *N*: 73 g per liter.

Nickel sulfate, $NiSO_4 \cdot 6H_2O$—0.5*N*: 66 g per liter.

Nitramine, picrylmethylnitramine, 2,4,6-trinitrophenylmethyl nitramine (indicator): dissolve 0.1 g in 60 ml alcohol and dilute with water to 100 ml; pH range colorless 10.8—13.0 red-brown; the solution should be kept in the dark as nitramine is unstable; on boiling with alkali it decomposes quickly. Fresh solutions should be prepared every few months.

Nitric acid, HNO_3—5*N*: 315 g per liter; sp. gr. 1.165. See also *Titrimetric Solutions.*

Nitrohydrochloric acid: see *aqua regia.*

***p*-Nitrophenol** (indicator): dissolve 0.2 g in 100 ml water; pH range colorless at about 5—7 yellow.

Nitroso-β-naphthol, $HOC_{10}H_6NO$—saturated solution: saturate 100 ml of 50% acetic acid with the solid.

Nylander's solution (detection of glucose): dissolve 40 g of rochelle salt and 20 g of bismuth subnitrate in 1000 ml of an 8% NaOH solution.

Obermayer's reagent (detection of indoxyl in urine): dissolve 4 g of $FeCl_3$ in a liter of concentrated HCl.

Orange III (indicator): see under *methyl orange.*

Oxalic acid, $H_2C_2O_4 \cdot 2H_2O$: dissolve in ten parts of water. See also *Titrimetric Solutions.*

Pavy's solution (estimation of glucose): mix 120 ml of Fehling's solution and

LABORATORY SOLUTIONS

300 ml of ammonium hydroxide (sp. gr. 0.88), and dilute to a liter with water.

Perchloric acid, $HClO_4$—60%: use as purchased.

Phenol solution: dissolve 20 *g* of phenol (carbolic acid) in a liter of water.

Phenol red, phenol-sulfonphthalein (indicator): dissolve 0.1 g in 14.20 ml 0.02*N* NaOH and dilute with water to 250 ml; or, 0.1 g in 100 ml 20% alcohol; pH range yellow 6.8—8.0 red.

Phenolphthalein (indicator): dissolve 1 g in 60 ml of alcohol and dilute with water to 100 ml; pH range colorless 8.2—10.0 red.

Phenol sulfonic acid (determination of nitrogen as nitrate; water analysis for nitrate): dissolve 25 grams of pure, white phenol in 150 ml of pure concentrated H_2SO_4, add 75 ml of fuming H_2SO_4 (15% SO_3), stir well and heat for two hours at 100°C.

Phosphoric acid, *ortho*, H_3PO_4—0.5*N*: 16 g per liter.

Poirrer blue C4B (indicator): dissolve 0.2 *g* in 100 ml water; pH range blue 11.0—13.0 red.

Potassium acid antimonate, KH_2SbO_4—0.1*N*: boil 23 g of the salt with 950 ml of water for 5 minutes, cool rapidly and add 35 ml of 6*N* KOH; allow to stand for one day, filter, dilute filtrate to a liter.

Potassium arsenate, K_3AsO_4—0.5*N* ($K_3AsO_4/10$): 26 g per liter.

Potassium arsenite, $KAsO_2$—0.5*N* ($KAsO_2/6$): 24 g per liter.

Potassium bromate, $KBrO_3$—0.5*N* ($KBrO_3/12$): 14 g per liter.

Potassium bromide, KBr—0.5*N*: 60 g per liter.

Potassium carbonate, K_2CO_3—3*N*: 207 g per liter.

Potassium chloride, KCl—0.5*N*: 37 g per liter.

Potassium chromate, K_2CrO_4—0.5*N*: 49 g per liter.

Potassium cyanide, KCN—0.5*N*: 33 g per liter. See also *Titrimetric Solutions*.

Potassium dichromate, $K_2Cr_2O_7$—0.5*N* ($K_2Cr_2O_7/8$): 38 *g* per liter. See also *Titrimetric Solutions*.

Potassium ferricyanide, $K_3Fe(CN)_6$—0.5*N*: 55 g per liter.

Potassium ferrocyanide, $K_4Fe(CN)_6 \cdot 3H_2O$—0.5*N*: 53 g per liter.

Potassium hydroxide, KOH—5*N*: 312 g per liter. See also *Titrimetric Solutions*.

Potassium iodate, KIO_3—0.5*N* ($KIO_3/12$): 18 *g* per liter. See also *Titrimetric Solutions*.

Potassium iodide, KI—0.5*N*: 83 g per liter.

Potassium nitrate, KNO_3—0.5*N*: 50 g per liter.

Potassium nitrite, KNO_2—6*N*: 510 g per liter.

Potassium permanganate, $KMnO_4$—0.5*N* ($KMnO_4/10$): 16 *g* per liter. See also *Titrimetric Solutions*.

Potassium pyrogallate (oxygen in gas analysis): weigh out 5 g of pyrogallol (pyrogallic acid), and pour upon it 100 ml of a KOH solution. If the gas contains less than 28% of oxygen, the KOH solution should be 500 g KOH in a liter of water; if there is more than 28% of oxygen in the gas, the KOH solution should be 120 g of KOH in 100 ml of water.

Potassium sulfate, K_2SO_4—0.5*N*: 44 g per liter.

Potassium thiocyanate, KCNS—0.5*N*: 49 g per liter.

Precipitating reagent (for group II, anions): dissolve 61 g of $BaCl_2 \cdot 2H_2O$ and 52 g of $CaCl_2 \cdot 6H_2O$ in water and dilute to one liter. If the solution becomes turbid, filter and use filtrate.

Quinaldine red (indicator): dissolve 0.1 g in 100 ml alcohol; pH range colorless 1.4—3.2 red.

Quinoline blue, cyanin (indicator): dissolve 1 g in 100 ml alcohol; pH range colorless 6.6—8.6 blue.

Rosolic acid, aurin, corallin, corallinphthalein, 4,4′-dihydroxy-fuchsone, 4,4′-dihydroxy-3-methyl-fuchsone (indica-

tor): dissolve 0.5 g in 50 ml alcohol and dilute with water to 100 ml.

Salicyl yellow (indicator): see *alizarin yellow GG*.

Scheibler's reagent (precipitates alkaloids, albumoses and peptones): dissolve sodium tungstate in boiling water containing half its weight of phosphoric acid (sp. gr. 1.13); on evaporation of this solution, crystals of phosphotungstic acid are obtained. A 10% solution of phosphotungstic acid in water constitutes the reagent.

Schweitzer's reagent (dissolves cotton, linen, and silk, but not wool): add NH_4Cl and NaOH to a solution of copper sulfate. The blue precipitate is filtered off, washed, pressed, and dissolved in ammonia (sp. gr. 0.92).

Silver nitrate, $AgNO_3$—0.25*N*: 43 g per liter. See also *Titrimetric Solutions*.

Silver sulfate, Ag_2SO_4—*N*/13 (saturated solution): stir mechanically 10 g of the salt in a liter of water for 3 hours; decant and use the clear liquid.

Soap solution (for hardness in water): (*a*) *Clark's or A.P.H.A. Stand. Methods* —prepare stock solution of 100 g of pure powdered castile soap in a liter of 80% ethyl alcohol; allow to stand over night and decant. Titrate against $CaCl_2$ solution (0.5 g $CaCO_3$ dissolved in a concentrated HCl, neutralized with NH_4OH to slight alkalinity using litmus as the indicator, make up to 500 ml; 1 ml of this solution is equivalent to 1 mg $CaCO_3$) and dilute with 80% alcohol until 1 ml of the resulting solution is equivalent to 1 ml of the standard $CaCl_2$ making due allowance for the lather factor (the lather factor is that amount of standard soap solution required to produce a permanent lather in a 50 ml portion of distilled water). One ml of this solution after subtracting the lather factor is equivalent to 1 mg of $CaCO_3$. (*b*) *Boutron-Boudet*—dissolve 100 g of pure castile soap in about 2500 ml of 56% ethyl alcohol and adjust so that 2.4 ml will give a permanent lather with 40 ml of a solution containing 0.59 g $Ba(NO_3)_2$ per liter of water; 2.4 ml of this solution is equivalent to 22 French degrees or 220 parts per million of hardness (as $CaCO_3$) on a 40 ml sample of water.

Sodium acetate, $NaC_2H_3O_2 \cdot 3H_2O$: dissolve 1 part of the salt in 10 parts of water.

Sodium acetate, acid: dissolve 100 g of sodium acetate and 30 ml of glacial acetic acid in water and dilute to one liter.

Sodium bismuthate (oxidation of manganese): heat 20 parts of NaOH nearly to redness in an iron or nickel crucible, and add slowly 10 parts of basic bismuth nitrate which has been previously dried. Add 2 parts of sodium peroxide, and pour the brownish-yellow fused mass on an iron plate to cool. When cold break up in a mortar, extract with water, and collect on an asbestos filter.

Sodium carbonate, Na_2CO_3—3*N*: 159 g per liter; one part Na_2CO_3, or 2.7 parts of the crystalline $Na_2CO_3 \cdot 10H_2O$ in 5 parts of water.

Sodium chloride, NaCl—0.5*N*: 29 g per liter. See also *Titrimetric Solutions*.

Sodium chloroplatinite, Na_2PtCl_4: dissolve 1 part of the salt in 12 parts of water.

Sodium cobaltinitrite, $Na_3Co(NO_2)_6$ —0.3*N*: dissolve 230 g of $NaNO_2$ in 500 ml of water, add 160 ml of 6*N* acetic acid and 35 g of $Co(NO_3)_2 \cdot 6H_2O$. Allow to stand one day, filter, and dilute the filtrate to a liter.

Sodium hydrogen phosphate, $Na_2HPO_4 \cdot 12H_2O$—0.5*N*: 60 g per liter.

Sodium hydroxide, NaOH—5*N*: 220 g per liter. See also *Titrimetric Solutions*.

Sodium hydroxide, alcoholic: dissolve 20 g of NaOH in alcohol and dilute to one liter with alcohol.

Sodium hypobromite: dissolve 100 g of NaOH in 250 ml of water and add 25 ml of bromine.

Sodium nitrate, $NaNO_3$—0.5*N*: 43 g per liter.

Sodium nitroprusside (for sulfur detection): dissolve about one gram of sodium nitroprusside in 10 ml of water; as the solution deteriorates on standing,

only freshly prepared solutions should be used. This compound is also called sodium nitroferricyanide and has the formula $Na_2Fe(NO)(CN)_5 \cdot 2H_2O$.

Sodium polysulfide, Na_2S_x: dissolve 480 g of $Na_2S \cdot 9H_2O$ in 500 ml of water, add 40 g of NaOH and 18 g of sulfur, stir mechanically and dilute to one liter with water.

Sodium sulfate, Na_2SO_4—0.5*N*: 35 g per liter.

Sodium sulfide, Na_2S; saturate NaOH solution with H_2S, then add as much NaOH as was used in the original solution.

Sodium sulfite, $Na_2SO_3 \cdot 7H_2O$—0.5*N*: 63 g per liter.

Sodium sulfite, acid (saturated): dissolve 600 g of $NaHSO_3$ in water and dilute to one liter; for the preparation of addition compounds with aldehydes and ketones: prepare a saturated solution of sodium carbonate in water and saturate with sulfur dioxide.

Sodium tartrate, acid, $NaHC_4H_4O_6$: dissolve 1 part of the salt in 10 parts of water.

Sodium thiosulfate, $Na_2S_2O_3 \cdot 5H_2O$: one part of the salt in 40 parts of water. See also *Titrimetric Solutions*.

Sonnenschein's reagent (alkaloid detection): a nitric acid solution of ammonium molybdate is treated with phosphoric acid. The precipitate so produced is washed and boiled with aqua regia until the ammonium salt is decomposed. The solution is evaporated to dryness and the residue is dissolved in 10% HNO_3.

Stannic chloride, $SnCl_4$—0.5*N*: 33 g per liter.

Stannous chloride, $SnCl_2 \cdot 2H_2O$—0.5*N*: 56 g per liter. The water should be acid with HCl and some metallic tin should be kept in the bottle.

Starch solution (iodine indicator): dissolve 5 g of soluble starch in cold water, pour the solution into 2 liters of water and boil for a few minutes. Keep in a glass-stoppered bottle.

Starch solution (other than soluble): make a thin paste of the starch with cold water, then stir in 200 times its weight of boiling water, and boil for a few minutes. A few drops of chloroform added to the solution acts as a preservative.

Stoke's reagent: dissolve 30 g of ferrous sulfate and 20 g of tartaric acid in water and dilute to one liter. When required for use, add strong ammonia until the precipitate first formed is dissolved.

Strontium chloride, $SrCl_2 \cdot 6H_2O$—0.5*N*: 67 g per liter.

Strontium nitrate, $Sr(NO_3)_2$—0.5*N*: 53 g per liter.

Strontium sulfate, $SrSO_4$: prepare a saturated solution.

Sulfanilic acid (for detection of nitrites): dissolve 8 g of sulfanilic acid in one liter of acetic acid (sp. gr. 1.04).

Sulfuric acid, H_2SO_4—5*N*: 245 g per liter, sp. gr. 1.153. See also *Titrimetric Solutions*.

Sulfurous acid, H_2SO_3: saturate water with sulfur dioxide.

Tartaric acid, $H_2C_4H_4O_6$: dissolve one part of the acid in 3 parts of water; for a saturated solution dissolve 750 g of tartaric acid in water and dilute to one liter.

Tannic acid: dissolve one g of tannic acid in one ml of alcohol and make up to 10 ml with water.

Tetrabromophenol blue, tetrabromophenol-tetrabromosulfonphthalein (indicator): dissolve 0.1 g in 5 ml 0.02*N* NaOH and dilute with water to 250 ml; pH range yellow 3.0—4.6 blue.

Thymol blue, thymol-sulfonphthalein (indicator): dissolve 0.1 g in 10.75 ml 0.02*N* NaOH and dilute with water to 250 ml; or, dissolve 0.1 g in 20 ml warm alcohol and dilute with water to 100 ml; pH range (acid) red 1.2—2.8 yellow, and (alkaline) yellow 8.0—9.6 blue.

Thymolphthalein (indicator): dissolve 0.1 g in 100 ml alcohol; pH range colorless 9.3—10.5 blue.

Tincture of iodine (antiseptic): add 70 g of iodine and 50 g of KI to 50 ml of water; make up to one liter with alcohol.

LABORATORY SOLUTIONS

o-Tolidine solution (for residual chlorine in water analysis): dissolve 1 g of pulverized o-tolidine, m.p. 129°C., in one liter of dilute hydrochloric acid (100 ml conc. HCl diluted to one liter).

Toluylene red (indicator): see *neutral red.*

Trichloroacetic acid: dissolve 100 g of the acid in water and dilute to one liter.

Trinitrobenzene, 1,3,5-trinitrobenzene (indicator): dissolve 0.1 g in 100 ml alcohol; pH range colorless 11.5—14.0 orange.

Trinitrobenzoic acid, 2,4,6-trinitrobenzoic acid (indicator): dissolve 0.1 g in 100 ml water; pH range colorless 12.0—13.4 orange-red.

Tropeolin D (indicator): see *methyl orange.*

Tropeolin O, sodium 2,4-dihydroxyazobenzene-4′-sulfonate (indicator): dissolve 0.1 g in 100 ml water; pH range yellow 11.0—13.0 orange-brown.

Tropeolin OO, orange IV, sodium *p*-diphenylamino-azobenzene sulfonate, sodium 4′-anilino-azobenzene-4-sulfonate (indicator): dissolve 0.1 g in 100 ml water; pH range red 1.3—3.2 yellow.

Tropeolin OOO, sodium α-naphtholazobenzene sulfonate (indicator): dissolve 0.1 g in 100 ml water; pH range yellow 7.6—8.9 red.

Turmeric paper (gives a rose-brown coloration with boric acid); wash the ground root of turmeric with water and discard the washings. Digest with alcohol and filter, using the clear filtrate to impregnate white, unsized paper, which is then dried.

Uffelmann's reagent (gives a yellow coloration in the presence of lactic acid): add a ferric chloride solution to a 2% phenol solution until the solution becomes violet in color.

Wagner's solution (phosphate rock analysis): dissolve 25 g of citric acid and one g of salicylic acid in water, and make up to one liter. Twenty-five to 50 ml of this reagent prevents precipitation of iron and aluminum.

Wijs solution (for iodine number): dissolve 13 g of resublimed iodine in one liter of glacial acetic acid (99.5%), and pass in washed and dried (over or through H_2SO_4) chlorine gas until the original thio titration of the solution is not quite doubled. There should be only a slight excess of iodine and no excess of chlorine. Preserve the solution in amber colored bottles sealed with paraffin. Do not use the solution after it has been prepared for more than 30 days.

Xylene cyanole-methyl orange indicator, Schoepfle modification (for partially color blind operators): dissolve 0.75 g of xylene cyanole FF (Eastman No. T 1579) and 1.50 g methyl orange in one liter of water.

***p*-Xylenol blue,** 1,4-dimethyl-5-hydroxybenzene-sulfonphthalein (indicator): dissolve 0.1 g in 250 ml alcohol; pH range (acid) red 1.2—2.8 yellow, and (alkaline) yellow 8.0—9.6 blue.

Zinc chloride, $ZnCl_2$—0.5*N*: 34 g per liter.

Zinc nitrate, $Zn(NO_3)_2 \cdot 6H_2O$—0.5*N*: 74 g per liter.

Zinc sulfate, $ZnSO_4 \cdot 7H_2O$—0.5*N*: 72 g per liter.

TRUE CAPACITY OF GLASS VESSELS

Based on the following coefficients of cubical expansion of glass, for: Pyrex 774 = 9.6×10^{-6}; Kimble N-51A = 15×10^{-6}; and Soda Lime = 25×10^{-6}.

The capacity of a glass vessel may be obtained by determining the weight of a contained liquid. The true capacity of glass vessels when their contents of water are weighed in air with brass weights can be found by means of the following equation:

$$V_t^\circ = W_t^\circ \times C_{\text{at } t^\circ c}.$$

where V_t° is the volume of the flask at t° C. when it contains W grams of water at t° C., and where C is read from the table below. Thus, if the contents of a glass flask filled with water weigh 100 grams at 15° C., then the true volume of the flask at 15° C. is 100 × 1.001935, or 100.1935 ml.

If it is desired to find the true volume of a glass flask at a temperature of T° C. when its contents are weighed at some other temperature of t° C., the following equation is used:

$$V_T^\circ = W_t^\circ \times C_{\text{at } t^\circ}(1 + C_{\text{at } T-t})$$

where V_T° is the true volume of the vessel at T° C. when it contains W grams of water at t° C., and $C_{\text{at } t^\circ}$ and $C_{\text{at } T-t}$ are values read from the table below. If $(T - t)$ is positive the constant $C_{\text{at } T-t}$ is positive; if $(T - t)$ is negative the constant $C_{\text{at } T-t}$ is negative. Thus, if the contents of a soda lime glass flask filled with water at 15° C. (t°) weigh 100 grams (W_t°), $C_{(\text{at } 25^\circ-15^\circ)}$ is 0.000250 and the true volume of the flask at 25° C. (V_T°) is 100 × 1.001935(1 + 0.000250), or 100.2185 ml.

When a flask is to be calibrated to contain a definite volume at a given temperature, the same equations are used but in this case the volume (V) is known and the equations are solved for the unknown weight (W) of contained liquid.

When mercury replaces water as the contained liquid of the vessel the value C for mercury is used.

C When Filled With

The table above shows the volume to which a more concentrated solution must be diluted to obtain the desired more dilute solution. Thus, 100 cc of a solution containing 15% of solute must be diluted to 300 cc to obtain a concentration of 5% and diluted to 150 cc to obtain a concentration of 10%. To prepare 1000 cc of a 5% solution by dilution of a 15% solution: (1000/300) $\times$100 or 333.33 cc of the 15% solution are diluted to 1000 cc.

EQUATIONS AND EQUIVALENTS FOR TITRIMETRIC (VOLUMETRIC) ANALYSIS

Aluminum

(1) $Al_2(SO_4)_3 + 6KOH = 2Al(OH)_3 + 3K_2SO_4$

$$KOH \Leftrightarrow \frac{Al}{3} \Leftrightarrow \frac{Al_2O_3}{6} \Leftrightarrow \frac{Al_2(SO_4)_3}{6}$$

(2) $Al_2(SO_4)_3 + 5KI + KIO_3 + 3H_2O = 2Al(OH)_3 + 3K_2SO_4 + 3I_2$

$$I \Leftrightarrow \frac{Al}{3} \Leftrightarrow \frac{Al_2(SO_4)_3}{6}$$

Antimony

(3) $H_3SbO_4 + 2HI = H_3SbO_3 + H_2O + I_2$

$$I \Leftrightarrow \frac{Sb}{2} \Leftrightarrow \frac{H_3SbO_4}{2}$$

(4) $SbCl_5 + 2KI = SbCl_3 + 2KCl + I_2$

$$I \Leftrightarrow \frac{Sb}{2} \Leftrightarrow \frac{Sb_2O_5}{4}$$

(5) $Sb_2O_5 + 4HI = Sb_2O_3 + 2H_2O + 2I_2$

$$I \Leftrightarrow \frac{Sb}{2} \Leftrightarrow \frac{Sb_2O_5}{4}$$

(6) $Sb_2S_5 + 6HCl = 2SbCl_3 + 2S + 3H_2S$

$3H_2S + 3I_2 = 6HI + 3S$

$$I \Leftrightarrow \frac{Sb}{3} \Leftrightarrow \frac{Sb_2S_5}{6}$$

TITRIMETRIC FACTORS AND THEIR LOGARITHMS

ACIDS*

The following factors are the equivalent of one milliliter of *normal acid*. Where the normality of the solution which is being used is other than normal multiply the factors given in the table below by the normality of the solution employed.

The equivalents of the esters are based on the results of saponification.

The indicators methyl orange and phenolphthalein are indicated by the abbreviations MO and PH respectively.

**For the most recent atomic weights see inside of back cover.

†In alcoholic soln., using methyl red or bromothymol blue as the indicator.

GRAVIMETRIC FACTORS AND THEIR LOGARITHMS

Based on the 1957 International Atomic Weights.*

In the table below the elements are arranged in alphabetical order.

Example:—To convert a given weight of Al_2O_3 to its equivalent of Al multiply by the factor at the right, 0.52923; similarly to convert Al to Al_2O_3, multiply by the factor at the left, 1.8895. For convenience in computation, the corresponding logarithms are given in each case.

Log. of factor +10	Factor		Factor	Log. of factor +10
		ALUMINUM Al = 26.98		
9.87488	0.74979	$Al \leftrightarrow Al_4C_3$	1.3339	10.12512
8.76881	0.058723	$Al \leftrightarrow Al(C_9H_6ON)_3$ (oxinate)	17.029	11.23119
9.81839	0.65824	$Al \leftrightarrow AlN$	1.5192	10.18161
10.27636	1.8895	$Al_2O_3 \leftrightarrow Al$	0.52923	9.72364

CUPROUS OXIDE AND COPPER EQUIVALENT OF DEXTROSE, INVERT SUGAR, LACTOSE AND MALTOSE *

Method of Munson and Walker, *Jour. Amer. Chem. Soc.* 28, 663, (1906).

Twenty five ml. (25 ml.) of Fehling Solution A and 25 ml. of Fehling Solution B as modified by the Assoc. of Official Agricultural Chemists (for preparation of these solutions see under *Special Reagents and Solutions*) are added to 50 ml. of the sugar solution in a 400 ml. beaker (when a smaller volume of sugar solution must be used, sufficient water must be added to make the final volume of solution 100 ml.) and the mixture heated at such a rate that a boiling temperature is obtained in four minutes and the boiling continued for exactly two minutes longer, keeping the beaker covered with a watch glass throughout the entire time of heating; the mixture is immediately filtered with suction through a Gooch crucible, washing the precipitated cuprous oxide first with water at 60°C., then with 10 ml. of alcohol and finally with 10 ml. of ether; after drying for 30 minutes at 100°C. and cooling in a desiccator it is weighed as cuprous oxide.

(Values in the Table Expressed in Milligrams)

Cuprous Oxide (Cu_2O)	Copper (Cu)	Dextrose (*d*-Glucose)	Invert Sugar	Lactose $C_{12}H_{22}O_{11}+H_2O$	Maltose $C_{12}H_{22}O_{11}+H_2O$

MUNSON-WALKER REDUCING-SUGAR VALUES

Cf. Lester D. Hammond, *Jour. Res. Natl. Bu. Stand. 24, 579 (1940).*

Sugars of higher purity than those originally used in making up the Munson-Walker determinations having become available, a redetermination of the earlier work has been made by Hammond. To this have been added the values for levulose, as well as the values for an additional sugar mixture containing 0.3 g. of total sugar. This latter mixture extends the adaptability of the method to include such products as simulated molasses, which contain such high percentages of invert sugar in the total sugar present that neither column of sugar-mixture values in the original Munson-Walker table was directly applicable. The invert sugar used in the determination of the values given in the following table were prepared by taking equal weights of crystalline dextrose and levulose. The conditions of the Munson-Walker method [1] were followed, except that the copper was determined electrolytically and the solution was heated by electricity.

The 400 ml. beaker is placed in an electric heater such that the 100 ml. of solution it contains is entirely surrounded by a nest of the resistance wire. The electric current is adjusted so that the solution can be brought to boiling in the 4-minute interval used in the method to within ±5 seconds.

The cuprous oxide is transferred to a Gooch crucible, washed, and then dissolved by the slow dropwise addition of 5 ml. of 1:1 nitric acid. The copper nitrate is received in a 250 ml. beaker, and 10 ml. of 1:1 nitric acid added, as well as about 5 g. of ammonium sulfate. Enough water to cover the cylindrical platinum-gauze electrodes is added, making the total volume of electrolyte about 180 ml. The electrolysis is conducted for about 36 hours [2] at a current density of approximately 0.10 amp./sq. dm.; and upon completion, as indicated by the ferrocyanide test, the electrolyte is displaced with distilled water before breaking the current. The copper deposit is washed with alcohol, dried for 15 minutes at 100°C., cooled in a desiccator, and weighed.[3]

(Values in the Table Expressed in Milligrams) [4]

34	38.3	16.2	17.3	15.5	15.1	9.0	17.9

[1] See preceding table.

[2] The electrolysis can be completed overnight by using a larger current. Cf. Sherrer, Bell, and Mogerman, *Jour. Res. Natl. Bu. Stand. 22, 697 (1939).*

[3] In the routine analysis of sugar products, any method of determining copper which is suitable to the products may be used.

[4] The values in the table for concentrations of reducing sugar less than 20 mg are extrapolated and should be used with caution and only for approximate determinations.

REDUCTION VALUES OF GLUCOSE IN BLOOD

Method of Hagedorn and Jensen, *Biochem. Zeit*, 135, 46; 137, 92 (1923).

Required solutions. *Aklaline ferricyanide*, 1.65 g potassium ferricyanide, and 10.6 g anhydrous sodium carbonate in 1000 cc of water; *acetic acid* (3%), 15 g glacial acetic acid in 485 cc of water; *iodide-sulfate*, 5 g potassium iodide, 50 g sodium chloride and 10 g zinc sulfate in sufficient water to make 200 cc of solution; 2.25 g *zinc sulfate* in sufficient water to make 500 cc of solution; standard 0.005 *N sodium thiosulfate*; standard 0.1 *N sodium hydroxide*; starch indicator solution.

Procedure. This method depends upon the reduction of potassium ferricyanide in alkaline solution by the glucose in the blood with subsequent titration of excess unreduced ferricyanide according to the reaction: $2H_3Fe(CN)_6 + 2HI = 2H_4Fe(CN)_6 + I_2$. One cc of 0.1 *N* sodium hydroxide and 5 cc of 0.45% zinc sulfate are mixed in a 15×150 mm test tube and to this is added 0.1 cc of blood from a capillary pipette which is then washed out with the mixture in the test tube; after heating this mixture for three minutes in a boiling water bath, then filtering through cotton into a 30×90 mm test tube and washing the filter with two 3 cc portions of distilled water, 2 cc of alkaline ferricyanide solution is added and the heating continued in the boiling water bath for 15 minutes; after cooling, adding 3 cc of the iodide-sulfate solution and 2 cc of 3% acetic acid solution, it is titrated with 0.005 *N* sodium thiosulfate with starch indicator.

Methods of Somogyi, *J. Biol. Chem.* 70, 599 (1926).

For 1:10 Blood Filtrate

Required solutions. *Copper reagent*, 6.5 g crystalline copper sulfate, 12 g rochelle salt, 20 g anhydrous sodium carbonate, 10 g potassium iodide, 0.08 g potassium iodate, 18 g potassium oxalate, 25 g sodium bicarbonate and sufficient water to make one liter of solution. *Sulfuric acid*, 5 *N*. Standard sodium thiosulfate, 0.005 *N*.

Procedure. Five cc of the sugar solution (containing between 0.1 and 2.0 milligrams of glucose) is added to 5 cc of copper reagent in a 25×250 mm test tube, then heated for 15 minutes in a boiling water bath; after cooling to 35°C and mixing with 1 cc 5 *N* sulfuric acid, it is titrated two minutes later with 0.005 *N* sodium thiosulfate. A blank titration using 5 cc of water in place of the blood is run simultaneously.

For 1:15 Filtrate

Required solutions. *Sulfuric acid*, 0.067 *N* and 2 *N*. 2.5% *sodium tungstate* solution. *Copper reagent* prepared as described above. Standard *sodium thiosulfate*, 0.005 *N*.

Procedure. Two tenths (0.2) cc of blood is added to 2 cc of 0.067 *N* sulfuric acid in a test tube and the pipette washed several times with the mixture in the test tube; exactly 0.8 cc of 2.5% sodium tungstate is added, the mixture centrifugated and 2 cc of the liquid withdrawn with a pipette filtering the solution through a layer of cotton fastened over the end of the pipette; this 2 cc is added to exactly 2 cc of copper reagent in a 16×150 mm test tube, mixed and heated for 15 minutes in a boiling water bath; after cooling to 35°C, adding 1 cc of 2 *N* sulfuric acid, it is titrated with 0.005 *N* sodium thiosulfate. A blank using 0.2 cc of water in place of the blood is run simultaneously.

POLAROGRAPHY

The values in the column headed $E_{\frac{1}{2}}$ are the half-wave potentials in units of volts referred to the saturated calomel electrode. The values in the column headed I_d are for $i_d/C \cdot m^{2/3} \cdot t^{1/6}$, where i_d is the diffusion current in microamperes, C is the concentration in millimoles per liter, m is the rate of flow of mercury in milligrams per second, and t is the drop time in seconds. The term "too positive" means that the diffusion current starts from zero applied emf and that the potential involved is more positive than the oxidation potential of mercury.

POLAROGRAPHY

Half-wave Potentials of Organic Compounds at 25°C

Anodic waves are indicated in the half-wave column. The value in the column headed *n* indicates the number of electrons involved in the reduction or oxidation. Measurements made at temperatures other than 25°C are indicated by including the temperature value.

Common or Trade Name	Chemical Synonym	Formula
A acid	1, 7-Dihydroxy-naphthalene-3, 6-disulfonic acid	$C_{10}H_8O_8S_2$
Acenaphthenequinone	7, 8-Diketo-acenaphthene	$C_{12}H_6O_2$
3-Acenaphthol	3-Hydroxy-acenaphthene	$C_{12}H_{10}O$
Acetosol	Acetylene tetrachloride	$Cl_2CH{\cdot}CHCl_2$
Acetyl-H acid	8-Acetamido-1-naphthol-3, 6-disulfonic acid	$C_{12}H_{11}O_8NS_2$
Acrylic liquid	Methyl methacrylate	$CH_2{:}C(CH_3)CO_2CH_3$
Actol	Silver lactate	$AgC_3H_5O_3{\cdot}H_2O$
Adalin	Bromo-diethylacetyl urea	$(C_2H_5)_2CBr{\cdot}CO{\cdot}NHCONH_2$
Adorin	Formaldehyde	HCHO
Adronol acetate	Cyclohexanol acetate	$CH_3CO_2C_6H_{11}$
Aerngo	Copper acetate	$Cu(C_2H_3O_2)_2{\cdot}6H_2O$
Agnin, or agnolin	Anhydrous lanolin	.....
Air saltpeter	cf. Saltpeter	.....
Aldoform	Formaldehyde	HCHO
Alembroth	cf. Sal alembroth	.....
Alen's α-acid	cf. Freund's acid	.....
Alizarin assistant	cf. Turkey red oil	.....
Alumino-ferric	Mixed sodium and aluminum sulfates	.....
Amide powder	An explosive powder	40% KNO_3, 38% NH_4NO_3, 22% C
4-Amino-chrysoidine	2, 4, 4'-Triamino-azo-benzene	$C_{12}H_{13}N_5$
Aminoform	cf. Hexamin	.....
Amino-naphthol-δ	1-Amino-7-naphthol	$C_{10}H_9ON$
Amino-naphthol-disulfonic acid K	cf. K acid	.....
Amino-naphthol-disulfonic acid RR or 2R	cf. 2R acid	.....
Amino-naphthol-disulfonic acid SS	1-Amino-8-naphthol-2, 4-disulfonic acid	$C_{10}H_9O_7NS_2$
Amino-naphthol-sulfonic acid or G	2-Amino-8-naphthol-6-sulfonic acid	$C_{10}H_9O_4NS$
Amino-naphthol-sulfonic acid R	2-Amino-3-naphthol-6-sulfonic acid	$C_{10}H_9O_4NS$
Amino-naphthol-sulfonic acid S	1-Amino-8-naphthol-4-sulfonic acid	$C_{10}H_9O_4NS$
Amino-phenol-sulfonic acid III	3-Amino-phenol-4-sulfonic acid	$C_6H_7O_4NS$
Amino-phenol-sulfonic acid IV	3-Amino-phenol-6-sulfonic acid	$C_6H_7O_4NS$
Amino-phenol-sulfonic acid V	3-Amino-phenol-5-sulfonic acid	$C_6H_7O_4NS$
Amino-R acid	2-Naphthylamine-3,6-disulfonic acid	$C_{10}H_9O_6NS_2$
Ammoniated iron	Ferric ammoniochloride	2.5% $FeCl_3$ + 97.5% NH_4Cl
Amylum	Corn starch	$(C_6H_{10}O_5)_n$
Analite	Explosive mixture of gasoline and N_2O_4	.....
Andresen's acid	1-Naphthol-3,8-disulfonic acid or 2-Naphthylamine-4,7-disulfonic acid	$C_{10}H_9O_6NS_2$

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Animal Oil	cf. Bone Oil	.....
o-Anisidine	*o*-Methoxy-aniline	C_7H_9ON
Antimonine	Antimony lactate	$Sb(C_3H_5O_3)_3$
Antimony red, Antimony vermilion	Antimony pentasulfide or antimony oxysulfide	Sb_2S_5 or $Sb_2S_3+Sb_2O_3$
Antimony yellow	Basic lead antimonate	$PbO{\cdot}Sb_2O_5$
Ant oil (artificial)	Furfural	$C_4H_3O{\cdot}CHO$
Apple acid	Malic acid	$H_2C_4H_4O_5$
Aqua regia	Mixture of nitric and hydrochloric acids	HNO_3+3HCl
Aquadag	Colloidal solution of graphite	.....
Arctic essence	Methyl chloride	CH_3Cl
Argatoxyl	Silver atoxylate	$NH_2C_6H_4{\cdot}AsO{\cdot}AgO{\cdot}OH$
Armstrong and Wynne's acid	1-Naphthol-3-sulfonic acid	$C_{10}H_8O_4S$
Arnaudon's green	Chromic hydroxide combination with some acid as boric, phosphoric, etc.	.....
Ascarite	Sodium hydroxide deposited on inert material	NaOH
Atabrine	cf. Quinacrine hydrochloride	.....
Atoxyl	Sodium *p*-aminophenyl-arsonate	$NH_2C_6H_4AsO{\cdot}OH{\cdot}ONa$
Azure blue	cf. Cobalt blue	.....
Azure copper	cf. Copper carbonate blue	.....
B acid	1-Amino-8-naphthol-3,5-disulfonic acid	$C_{10}H_9O_7NS_2$
Bakelite	Phenol-formaldehyde condensation resin	.....
Ballistite	Smokeless powder	50% nitroglycerin and 50% collodion cotton
Baryta water	Barium hydroxide solution	$Ba(OH)_2+aq$
Bentonite	Impure aluminum silicate	.....
Benzine	Gasoline, petroleum ether	.....
Benzinoform	Carbon tetrachloride	CCl_4
Benzoline	cf. Naphtha, petroleum	.....
Bicarburetted hydrogen	Ethylene	C_2H_4
Bichrome	Potassium (or sodium) dichromate	K_2(or Na_2)Cr_2O_7
Bismuth white	Bismuth subnitrate or bismuth oxychloride	$BiONO_3{\cdot}H_2O$ or BiOCl
Bismuth yellow	Bismuth chromate	$Bi_2(CrO_4)_3$
Black ash	Impure sodium carbonate	Na_2CO_3
Black flux	Mixture of potassium carbonate and carbon	K_2CO_3 and C
Blau gas	Blue gas	44% CH_4, 52% H_2
Blue malachite	cf. Copper carbonate blue	.....
Boletic acid	Fumaric acid	$(CH{\cdot}CO_2H)_2$
Bone black	Animal charcoal	C
Bone oil	Mixture of pyrrole, pyridine, quinoline, fatty acids and nitriles, amines, and hydrocarbons from distillation of bones	.....
Boroform	Acetylene tetrachloride	$(CHCl_2)_2$
Bremen blue	cf. Copper carbonate blue	.....
"Butter of"	Chloride of	.....
Butyl glycol	Glycol monobutyl ether	$HOC_2H_4OC_4H_9$
C acid	2-Naphthol-4,8-disulfonic acid	$C_{10}H_8O_7S_2$

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Calcic liver of sulfur	Calcium sulfide	CaS
Calgon	Sodium phosphate glass	$1.1Na_2O{\cdot}1P_2O_5$
Caliche	Impure sodium nitrate	$NaNO_3$
Calomel	Mercurous chloride	HgCl
Calx	Calcium oxide	CaO
Calx chlorinata	Calcium chloro-hypochlorite	CaClOCl
Canadol	cf. Naphtha, petroleum	.....
Canton's phosphorus	Calcium sulfide	CaS
Caoutchouc	Rubber	$(C_5H_8)_n$
Caput mortum	Ferric oxide, red	Fe_2O_3
Carbon chloride, Julin's	Hexachlorobenzene	C_6Cl_6
Carbon hexachloride	Hexachloroethane	C_2Cl_6
Carbonic acid	Carbon dioxide	CO_2
Carbonic anhydride	Carbon dioxide	CO_2
Carrene	Methylene chloride	CH_2Cl_2
"Caustic"	Hydroxide of	.....
Cellon	Acetylene tetrachloride	$(CHCl_2)_2$
Charlton white	cf. Lithopone	.....
Chinacrin	cf. Atabrin	.....
Chloride of soda	Sodium hypochlorite solution	NaOCl + aq.
Chloro-H acid	1-Chloro-8-naphthol-3,6-disulfonic acid	$C_{10}H_7O_7S_2Cl$
Cinnabar, Austrian	Basic lead chromate	$PbCrO_4{\cdot}PbO$
Cleve's α-acid	1-Naphthylamine-5-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's β-acid	1-Naphthylamine-6-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's γ-acid	1-Naphthylamine-3-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's δ-acid	1-Naphthylamine-7-sulfonic acid	$C_{10}H_9O_3NS$
Cleve's θ-acid	1-Naphthylamine-7-sulfonic acid	$C_{10}H_9O_3NS$
Cobalt blue	Oxides of cobalt and aluminum in varing proportions, or cobalt aluminate	.....
Cobalt green	Cobalt zincate	$CoZnO_2$
Cobalt violet	Cobaltous ammonium phosphate	$CoNH_4PO_4{\cdot}H_2O$
Cobalt yellow	Potassium cobaltinitrite	$Co(NO_2)_3{\cdot}3KNO_2{\cdot}1.5H_2O$
Cobalt ultramarine	cf. Cobalt blue	.....
Copper carbonate blue	Basic copper carbonate, composition variable	*ca.* $2CuCO_3{\cdot}Cu(OH)_2$
Cresolin; Cresotal	Carbonate esters of cresols, guaiacol, etc.	.....
Crocus of antimony	Antimony sulfide, or a slag obtained in refining antimony, mainly sodium or potassium thioantimonite	Sb_2S_3, or Na_3SbS_3 or K_3SbS_3
Crocus of Mars (or Martis)	A red-brown ferric oxide obtained by heating ferrous sulfate	Fe_2O_3
Cupren	Acetylene polymer	$(C_2H_2)_n$ + 0.2% to 0.3% Cu
Cystamine	cf. Hexamin	.....
Cystogen	cf. Hexamin	.....
Dahl's acid II	1-Naphthylamine-4,6-disulfonicacid	$C_{10}H_9O_6NS_2$
Dahl's acid III	1-Naphthylamine-4,7-disulfonic acid	$C_{10}H_9O_6NS_2$
de Haens salt	Mixture of sodium fluoride and antimony trifluoride	$NaF + SbF_3$
Dehydro-thio-*p*-toluidine	1-*p*(-Aminophenyl)-3-methyl-benzothiazole	$C_{14}H_{12}N_2S$
Depurated tartar	Pure potassium hydrogen tartrate	$KHC_4H_4O_6$
Dermatol	Basic bismutn gallate	$Bi(OH)_2C_7H_5O_5$
Detonal	Diethylacetyl urethane	$(C_2H_5)_2CHCONHCO_2C_2H_5$

TRADE NAMES OF CHEMICALS WITH SYNONYMS AND FORMULAS

Common or Trade Name	Chemical Synonym	Formula
Diapthol	*o*-Hydroxyquinoline-*m*-sulfonic acid	$HOC_9H_5NSO_3H$
Diatol	Diethyl carbonate	$(C_2H_5O)_2CO$
Dimethyl-gamma acid	2-Dimethylamino-8-naphthol-6-sulfonic acid	$C_{12}H_{13}O_4NS$
Diolin	Octadecanediol	$CH_3(CH_2)_5CHOH(CH_2)_{10}\cdot CH_2OH$
Dioxogen	cf. Bone oil	.....
Dippel's oil	cf. Bone oil	.....
Dissolvan CA or DN	Mixture of 60-80°C. boiling solvents for nitro- and acetyl-celluloses	.....
Disulfo acid E	1-Naphthol-3,8-disulfonic acid	$C_{10}H_8O_7S_2$
Disulfo acid F	2-Naphthylamine-3,7-disulfonic acid	$C_{10}H_7O_6NS_2$
Disulfuric acid	Fuming sulfuric acid	$H_2SO_4+SO_3$
Dowicide	Various chlorophenols	ClC_6H_4OH
Dragonic acid	Anisic acid	$CH_3O\cdot C_6H_4\cdot CO_2H$
DTS	Dehydrothio-*p*-toluidine sulfonic acid	$C_{14}H_{12}O_3N_2S_2$
Dulcose	Dulcitol	$C_6H_8(OH)_6$
Duresco	cf. Lithopone	.....
Eau-de-Javelle	Potassium hypochlorite solution	$KOCl+aq.$
Eau-de-Labarraque	Sodium hypochlorite solution	$NaOCl+aq.$
Elayl	Ethylene	C_2H_4
Emeraude green	cf. Guignet's green	.....
Enamel white	cf. Lithopone	.....
Epsilon acid or ϵ acid	1-Naphthylamine-3,8-disulfonic acid	$C_{10}H_9O_6NS_2$
	1-Naphthol-3,8-disulfonic acid	$C_{10}H_8O_7S_2$
	1, 8-Dihydroxy-naphthalene-3-sulfonic acid	$C_{10}H_8O_5S$
Erdmann's μ acid	1-Naphthylamine-6-sulfonic acid	$C_{10}H_9O_3NS$
Etherin	Ethylene	C_2H_4
Ethiops mineral	Impure black mercuric sulfide	*ca.* 60% $HgS+40\%$ S
Ethocel	Ethyl cellulose	.....
Ethyl F acid	2-Ethylaminonaphthalene-7-sulfonic acid	$C_{12}H_{13}O_3NS$
Ethyl-gamma acid	2-Ethylamine-8-naphthol-6-sulfonic acid	$C_{12}H_{13}O_4NS$
Euonymit	Dulcitol	$C_6H_8(OH)_6$
Everitt's salt	Potassium ferrous Ferrocyanide	$K_2Fe_2(CN)_6$
F acid	2-Naphthol-7-sulfonic acid	$C_{10}H_8O_4S$
	2-Naphthylamine-7-sulfonic acid	$C_{10}H_9O_3NS$
	2-Naphthylamine-3,-disulfonic acid	$C_{10}H_9O_6NS_2$
	2-Amino-7-naphthol-3-sulfonic acid	$C_{10}H_9O_4NS$
	2, 7-Dihydroxy-naphthalene-3-sulfonic acid	$C_{10}H_8O_5S$
Ferro prussiate	Any ferrocyanide, specifically potassium ferrocyanide	$K_4Fe(CN)_6$
Flake white	Bismuth subnitrate, or (in paint) white lead	$BiONO_3\cdot H_2O$ $2PbCO_3\cdot Pb(OH)_2$
"Flowers of" a metal	Oxide of the metal	.....
Fluoremetic	Antimony sodium fluoride	$SbF_3\cdot NaF$
Formalin	40% Formaldehyde	$HCHO+aq.$
Formalith	Kieselguhr soaked in formaldehyde solution	HCHO
Formin	cf. Hexamin	.....
Formitrol	Formaldehyde	HCHO

SOLUBILITY PRODUCT

In a saturated solution of any given salt, the product of the concentrations of the ions which are combining to form the salt, is a constant. If more than one ion of the same kind enters into the formation of one molecule of the compound then the concentration of that ion must be raised to a power equal to the number of such ions entering into one molecule of the compound. The concentrations are expressed as gram molecular concentrations per liter. For example, silver acetate has a solubility of 10.07 grams per liter at 16°C. Its molecular weight is 167 and it is 70.8% ionized. Therefore, its molar concentration would be 10.07/167 and since it is 70.8% ionized, the Ag ion concentration would be $10.07/167 \times 70.8\%$ or 0.0427. Since for each silver ion there is an acetate ion, the acetate ion concentration would be the same as for the silver ion. Hence the solubility product would be $0.0427 \times 0.0427 = 0.00182$ at 16 °C.

Substance	Formula	Temp. °C.	Solubility-Product
Aluminum hydroxide	$Al(OH)_3$	20°	1.9×10^{-33}
Aluminum hydroxide	$Al(OH)_3 \cdot 3H_2O$(as an acid)	20°	4×10^{-13}
Barium carbonate	$BaCO_3$	16°	7×10^{-9}
Barium carbonate	$BaCO_3$	18°	8.1×10^{-9}
Barium chromate	$BaCrO_4$	18°	1.6×10^{-10}
Barium chromate	$BaCrO_4$	28°	2.4×10^{-10}
Barium fluoride	BaF_2	9.5°	1.6×10^{-6}
Barium fluoride	BaF_2	18°	1.7×10^{-6}
Barium fluoride	BaF_2	25.8°	1.73×10^{-6}
Barium iodate	$Ba(IO_3)_2 \cdot 2H_2O$	10°	8.4×10^{-11}
Barium iodate	$Ba(IO_3)_2 \cdot 2H_2O$	25°	6.5×10^{-10}
Barium oxalate	$BaC_2O_4 \cdot 3\frac{1}{2}H_2O$	18°	1.62×10^{-7}
Barium oxalate	$BaC_2O_4 \cdot 2H_2O$	18°	1.2×10^{-7}
Barium oxalate	$BaC_2O_4 \cdot \frac{1}{2}H_2O$	18°	2.18×10^{-7}
Barium sulfate	$BaSO_4$	18°	0.87×10^{-10}
Barium sulfate	$BaSO_4$	25°	1.08×10^{-10}
Barium sulfate	$BaSO_4$	50°	1.98×10^{-10}
Cadmium oxalate	$CdC_2O_4 \cdot 3H_2O$	18°	1.53×10^{-8}
Cadmium sulfide	CdS	18°	3.6×10^{-29}
Calcium carbonate	$CaCO_3$	15°	0.99×10^{-8}
Calcium carbonate	$CaCO_3$	25°	0.87×10^{-8}
Calcium chromate	$CaCrO_4$	18°	2.3×10^{-2}
Calcium fluoride	CaF_2	18°	3.4×10^{-11}
Calcium fluoride	CaF_2	26°	3.95×10^{-11}
Calcium iodate	$Ca(IO_3)_2 \cdot 6H_2O$	10°	22.2×10^{-8}
Calcium iodate	$Ca(IO_3)_2 \cdot 6H_2O$	18°	64.4×10^{-8}
Calcium oxalate	$CaC_2O_4 \cdot H_2O$	18°	1.78×10^{-9}
Calcium oxalate	$CaC_2O_4 \cdot H_2O$	25°	2.57×10^{-9}
Calcium sulfate	$CaSO_4$	10°	6.1×10^{-5}
Calcium tartrate	$CaC_4H_4O_6 \cdot 2H_2O$	18°	0.77×10^{-6}
Cobalt sulfide	CoS	18°	3×10^{-26}
Cupric iodate	$Cu(IO_3)_2$	25°	1.4×10^{-7}
Cupric oxalate	CuC_2O_4	25°	2.87×10^{-8}
Cupric sulfide	CuS	18°	8.5×10^{-45}
Cuprous bromide	$CuBr$	18°	4.1×10^{-8}
Cuprous chloride	$CuCl$	18°	1.0×10^{-6}
Cuprous iodide	CuI	18°	5.0×10^{-12}
Cuprous sulfide	Cu_2S	16°-18°	2×10^{-47}
Cuprous thiocyanate	$CuSCN$	18°	1.6×10^{-11}
Ferric hydroxide	$Fe(OH)_3$	18°	1.1×10^{-36}
Ferrous hydroxide	$Fe(OH)_2$	18°	1.64×10^{-14}
Ferrous oxalate	FeC_2O_4	25°	2.1×10^{-7}
Ferrous sulfide	FeS	18°	3.7×10^{-19}

SOLUBILITY OF GASES IN WATER

The column headed "α" gives the volume of gas reduced to standard conditions (0°C and 760 mm) dissolved in one volume of water when the pressure of the gas (without the aqueous tension) is 760 mm; this value "α" is the "absorption coefficient." The column headed "l" gives the volume of the gas expressed in cubic centimeters dissolved in one volume of water at a total pressure (partial pressure of the gas plus the aqueous tension at the stated temperature) of 760 mm. The column headed "q" gives the weight of gas in grams dissolved in 100 grams of water at a total pressure (partial pressure of the gas plus the aqueous tension at the stated temperature) of 760 mm.

*Atmospheric Nitrogen containing 98.815% N_2 by volume + 1.185% inert gases.

SOLUBILITIES OF INORGANIC COMPOUNDS

This table shows the amount of anhydrous substance which is soluble in 100 grams of water at the temperature in degrees Centigrade as indicated; where the formula is preceded by † the value is expressed in grams of substance in 100 ml of saturated

	Substance	Formula	Solid Phase	0°C.	10°C.
1	**Aluminum** chloride	$AlCl_3$	$6H_2O$	.....	.....
2	sulfate	$Al_2(SO_4)_3$	$18H_2O$	31.2	33.5
3	**Ammonium** aluminum sulfate	$(NH_4)_2Al_2(SO_4)_4$	$24H_2O$	2.1	4.99

SEA WATER

Reprinted from *The Oceans*, by Sverdrup, Johnson, and Fleming, with permission from the publishers, Prentice-Hall, Inc., New York.

The table below lists all of the elements known to occur in sea water as dissolved solids, except hydrogen, oxygen and dissolved gases. They are not given as ions but as the amounts of the individual elements which occur in water of 19.00% chlorinity. Cadmium, chromium, cobalt and tin are merely mentioned because they have been found in the ash of marine organisms, and hence it is implied that they occur in sea water although so far they have not been obtained directly.

Element	parts per million, mg/kg	Element	parts per million, mg/kg
Chlorine	18980	Copper	0.001–0.01
Sodium	10561	Zinc	0.005
Magnesium	1272	Lead	0.004
Sulfur	884	Selenium	0.004
Calcium	400	Cesium	0.002
Potassium	380	Uranium	0.0015
Bromine	65	Molybdenum	0.0005
Carbon	28	Thorium	<0.0005
Strontium	13	Cerium	0.0004
Boron	4.6	Silver	0.0003
Silicon	0.02–4.0	Vanadium	0.0003
Fluorine	1.4	Lanthanum	0.0003
Nitrogen*	0.01–0.7	Yttrium	0.0003
Aluminum	0.5	Nickel	0.0001
Rubidium	0.2	Scandium	0.00004
Lithium	0.1	Mercury	0.00003
Phosphorus	0.001–0.10	Gold	0.000006
Barium	0.05	Radium	$0.2\text{–}3\times10^{-10}$
Iodine	0.05	Cadmium	
Arsenic	0.01–0.02	Chromium	
Iron	0.002–0.02	Cobalt	
Manganese	0.001–0.01	Tin	

* In dissolved compounds and not as dissolved atmospheric nitrogen.

The time for evaporation is based upon the time required to completely evaporate 0.5 cc of solvent on filter paper as compared with the corresponding time for ethyl ether which is given a value of 1.

*indicates that dilution causes cloudiness or precipitation.

† Other grades of shellac are less soluble.

RESIN SOLVENTS

s. = soluble in an equal weight of solvent at room or slightly raised temperature; Natural resins, especially gum benzoin, contain more or less insoluble impurities. i. = insoluble; i.s. = partly soluble.

ORGANIC SOLVENTS

In the table below the compounds are arranged in order of increasing boiling points. For methods of testing the purity, the purification, and the drying of many of the solvents listed below, the reader is referred to the monograph *ORGANIC SOLVENTS*, by Weissberger & Proskauer, Oxford University Press, London & New York, 1935.

Name	B. P. 760 mm °C
Ethyl chloride	13
Ethylene oxide	14
Furan	31–2
Methyl formate	32
Diethyl ether	34.6
Propylene oxide	35
n-Pentane	36.1
Ethyl bromide	38.4
Methylene chloride	40
Methylal	42.3
Carbon disulfide	46.3
Ethyl formate	54
Acetone	56.5
Methyl acetate	57.1
Ethylidene dichloride	57.3
Acetylene dichloride*	59–61
Ligroin (low boiling)	60–120
Chloroform	61.2
Methyl alcohol	64.7
Tetrahydrofuran	65–6
Di-*iso*-propyl ether	68.5–69.0
n-Hexane	68.7
iso-Butyl chloride	68.9
Trichloroethane (1,1,1)	74.1
Dioxolane	75–6
Carbon tetrachloride	76.8
Ethyl acetate	77.1
n-Butyl chloride	77.9
Ethyl alcohol	78.4
Methyl-ethyl ketone	79.6
2-Methyl-tetrahydrofuran	80.0
Benzene	80.1
Cyclohexane	80.7
n-Propyl formate	81.3
Acetonitrile	82
iso-Propyl alcohol	82.5
tert-Butyl alcohol	82.9
Cyclohexene	83.3
Ethylene chloride	83.7
Thiophene	84
Trichloroethylene	87.2
iso-Propyl acetate	88.4
iso-Butyl bromide	91.5
2,5-Dimethyl-furan	93–4
Ethyl chloroformate	94–5
Allyl alcohol	96.6
1,2-Dichloropropane	96.8
n-Propyl alcohol	97.8
n-Heptane	98.4
Ethyl propionate	99.1
sec-Butyl alcohol	99.5
iso-Amyl chloride	99.7
Ligroin (high boiling)	100–150
Formic acid	100.8
Methyl-cyclohexane	100.9
Dioxane (1,4)	101.1
Nitromethane	101.5
n-Propyl acetate	101.6
Diethyl ketone	101.7
tert-Amyl alcohol	102
Acetal	102.2
n-Butyl formate	106.9
iso-Butyl alcohol	107–8
Acetylene dibromide*	110
Toluene	110.6
sec-Butyl acetate	112–3
Trichloroethane (1,1,2)	113.5
Nitroethane	114.8
Pyridine	115–6
Pentan-3-ol	115.6
Epichlorohydrin	117
n-Butyl alcohol	117
iso-Butyl acetate	118
Methyl-*iso*-butyl ketone	118
Acetic acid	118.1
Propylene glycol monomethyl ether	119
Ethyl *n*-butyrate	120–1
2-Nitropropane	120.3
iso-Amyl bromide	120.4
Tetrachloroethylene	120.8

* Mixture of isomers.

ORGANIC SOLVENTS

Name	B. P. 760 mm °C

α-Propylene glycol	188–9
Ethyl benzyl ether	190
Glycol diacetate	190.5
Benzonitrile	190.7

† Slight decompn.

ORGANIC SOLVENTS

Name	B. P. 760 mm °C
Decalin*	191.7
Dimethylaniline	193
iso-Amyl *iso*-valerate	194
Octan-1-ol	194–5
Acetonyl acetone	194.1
Diethylene glycol monomethyl ether	194.2
Diethylene glycol monoethyl ether	195
Glycol	197.4
Methyl benzoate	198–9
Diethyl malonate	198.9
o-Toluidine	199.7
"Carbitol"	200.1
p-Toluidine	200.3
Acetophenone	203
Ethylene glycol dibutyl ether	203
Methyl-phenyl carbinol	203.9
Benzyl alcohol	204.7
Tetralin	206–7
Butan-1,3-diol	206.5
γ-Valerolactone	207–8
Ethylene glycol monomethyl ether acetal	207.2
Camphor	209.1
Diethylene glycol monomethyl ether acetate	209.1
o-Chloroaniline	210.5
Nitrobenzene	210.9
Ethyl benzoate	211–2
iso-Phorone	215–6
Diethylene glycol monoethyl ether acetate	217.7
Naphthalene	217.9
Acetamide	222
Methyl salicylate	222.2
Diethyl maleate	225
n-Propyl benzoate	231
Tributyl borate	231
Decan-1-ol	232.9
Benzyl cyanide	233–4
Quinoline	238
Ethylene glycol monophenyl ether (Phenyl Cellosolve)	244.7
Diethylene glycol	244.8
n-Dibutyl oxalate	245.5
Diethylene glycol monobutyl ether acetate	246.4
Triethylene glycol monoethyl ether	248
n-Butyl benzoate	250
Diethylene glycol mono-*n*-hexyl ether	252
Diethylene glycol di-*n*-butyl ether (Dibutyl Carbitol)	255
Triacetin	258–9
α-Chloronaphthalene	259.3
iso-Amyl benzoate	262
α-Monobutyrin	269–71
Ethyl cinnamate	271
o-Nitroanisole	272–3
Tetraethylene glycol dimethyl ether	275.8
iso-Amyl salicylate	277–8
α-Bromonaphthalene	281.1
Dimethyl phthalate	282
Glycerol	290
Triethylene glycol	290
Diethyl phthalate	298–9
Benzyl benzoate	323–4
Tetraethylene glycol dibutyl ether	330
n-Dibutyl phthalate	340

* Mixture of isomers.

HYDROMETERS

Various hydrometers and the relation between the various scales.

Alcoholometer. This hydrometer is used in determining the density of aqueous ethyl alcohol solutions; the reading in degrees is numerically the same as the percentage of alcohol by volume. The scale known as *Tralle* gives the precentage by volume. (See also formulas for conversion to percent by weight, percent by volume, and percent proof.) *Wine* and *Must* hydrometer relations are given below.

Ammoniameter. This hydrometer, employed in finding the density of aqueous ammonia solutions, has a scale graduated in equal divisions from 0° to 40°. To convert the reading to specific gravity multiply by 3 and subtract the resulting number from 1000.

Balling Hydrometer. See under **Saccharometer.**

Barkometer or **Barktrometer.** This hydrometer which is used in determining the density of tanning liquors has a scale from 0° to 80° Bk; the number to the right of the decimal point of a specific gravity reading is the corresponding Bk degree; thus, a specific gravity of 1.015 is 15°Bk.

Baumé Hydrometers. For liquids heavier than water.—This hydrometer was originally based on the density of a 10% sodium chloride solution which was given the value of 10° and the density of pure water which was given the value of 0°, the interval between these two values was divided into 10 equal parts. Other reference points have been taken with the result that so much confusion exists that there are about 36 different scales in use, many of which are incorrect. In general a Baumé hydrometer should have inscribed on it the temperature at which it was calibrated and also the temperature of the water used in relating the density to a specific gravity. The following expression gives the relation between the specific gravity and several of the Baumé scales:—

$$\text{Specific gravity} = \frac{m}{m - \text{Baumé}}$$

m = 145 at 60°/60°F (15.56°C) for the American Scale

m = 144 for the old scale used in Holland

m = 146.3 at 15°C for the Gerlach Scale

m = 144.3 at 15°C for the Rational Scale generally used in Germany

See also special table for conversion to density and Twaddell scale.

For liquids lighter than water.—Originally the density of a solution of 1 gram of sodium chloride in 9 grams of water at 12.5°C was given a value of 0°Bé and pure water a value of 10°Bé. The scale between these points was divided into ten equal parts and these divisions were repeated throughout the scale giving a relation which could be expressed by the formula: Specific gravity = 145.88/(135.88+Bé), which is approximately equal to 146/(136+Bé.) Other scales have since come into more general use such as that of the Bu. of Standards in which the specific gravity at 60°/60°F = 140/(130+Bé.) and that of the American Petroleum Institute (A.P.I. Scale) in which the specific gravity at 60°/60°F = 141.5/(131.5+API°.)

See also special table for conversion to density and Twaddell scale.

Beck's Hydrometer. This hydrometer is graduated to show a reading of 0° in pure water and a reading of 30° in a solution with a specific gravity of 0.850, with equal scale divisions above and below these two points.

Brix Hydrometer. See under Saccharometers.

Cartier's Hydrometer. This hydrometer shows a reading of 22° when immersed in a solution having a density of 22° Baumé but the scale divisions are smaller than on the Baumé hydrometer in the ratio of 16 Cartier to 15 Baumé.

Fatty Oil Hydrometer. The gradu-

ations on this hydrometer are in specific gravity within the range 0.908 to 0.938. The letters on the scale correspond to the specific gravity of the various common oils as follows: *R*, rape; *O*, olive; *A*, almond; *S*, sesame; *HL*, hoof oil; *HP*, hemp; *C*, cotton seed; *L*, linseed. See also Oleometer below.

Lactometers. These hydrometers are used in determining the density of milk. The various scales in common use are the following:

New York Board of Health has a scale graduated into 120 equal parts, 0° being equal to the specific gravity of water and 100° being equal to a specific gravity of 1.029.

Quevenne lactometer is graduated from 15° to 40° corresponding to specific gravities from 1.015 to 1.040.

Soxhlet lactometer has a scale from 25° to 35° corresponding to specific gravities from 1.025 to 1.035 respectively.

Oleometer. A hydrometer for determining the density of vegetable and sperm oils with a scale from 50° to 0° corresponding to specific gravities from 0.870 to 0.970. See also *Fatty Oil* hydrometer above.

Saccharometers. These hydrometers are used in determining the density of sugar solutions. Solutions of the same concentration but of different carbohydrates have very nearly the same specific gravity and in general a concentration of 10 grams of carbohydrate per 100 cc of solution shows a specific gravity of 1.0386. Thus, the wt. of sugar in 1000 ml soln. is, (a) For conc. <12g/100 ml: (wt. of 1000 ml soln. $-1000) \div 0.386$; (b) for conc. >12g/100 ml: (wt. of 1000 ml soln. $-1000) \div 0.385$.

Brix hydrometer is graduated so that the number of degrees is identical with the percentage by weight of cane sugar and is used at the temperature indicated on the hydrometer.

Balling's saccharometer is used in Europe and is practically identical with the Brix hydrometer.

Bates brewers' saccharometer which is used in determining the density of malt worts is graduated so that the divisions express pounds per barrel (32 gallons). The relation between degrees Bates (=b) and degrees Balling (=B) is shown by the following formula: $B = 260b/(360+b)$.

See also below under *Wine and Must*.

Salinometer. This hydrometer, which is used in the pickling and meat packing plants, is graduated to show percentage of saturation of a sodium chloride solution. An aqueous solution is completely saturated when it contains 26.4% pure sodium chloride. The range from 0% to 26.4% is divided into 100 parts, each division therefore representing 1% of saturation. In another type of salinometer, the degrees correspond to percentages of sodium chloride expressed in grams of sodium chloride per 100 cc of water.

Sprayometer (Parrot and Stewart).—This hydrometer which is used in determining the density of *lime sulfur* solutions has two scales; one scale is graduated from 0° to 38° Baumé and the other scale is from 1.000 to 1.350 specific gravity.

Tralle Hydrometer. See *alcoholometer* above.

Twaddell Hydrometer. This hydrometer which is used only for liquids heavier than water, has a scale such that when the reading is multiplied by 5 and added to 1000 the resulting number is the specific gravity with reference to water as 1000. To convert specific gravity at 60°/60°F to Twaddell degrees, take the decimal portion of the specific gravity value and multiply it by 200; thus a specific gravity of $1.032 = 0.032 \times 200 = 6.4°$ Tw. See also special table for conversion to density and Baumé scale.

Wine and Must Hydrometer—This instrument has three scales. One scale shows readings of 0° to 30° Brix for sugar (see Brix hydrometer above); another scale from 0° to 15° Tralle is used for sweet wines to indicate the percentage of alcohol by volume; and a third scale from 0° to 20° Tralle is used for tart wines to indicate the percentage of alcohol by volume.

SPECIFIC GRAVITY CORRECTIONS FOR THE BUOYANT EFFECT OF THE AIR

Determinations made with a pyknometer.

$$D_{vac} = \frac{W_2}{W_1} d - 0.0012 \left(\frac{W_2 d}{W_1} - 1 \right)$$

$$S_{vac} = \frac{W_2}{W_1} - 0.0012 \left(\frac{W_2}{W_1} - 1 \right)$$

Where

D_{vac} = density of the liquid in grams per milliliter at t°C corrected for the buoyant effect of air.

W_1 = weight in air of the water required to fill the pykometer at t°C.

W_2 = weight in air of the liquid required to fill the pyknometer at t°C.

d = density of water in grams per milliliter at t°C.

S_{vac} = specific gravity of the liquid at t°C. referred to water at t°C corrected for the buoyant effect of air.

When the weight of the water is determined at a temperature of t°C, and that of the liquid at a different temperature t′, the equations above are modified as follows:

$$D_{vac} = \frac{W_2}{W_1} d - 0.0012 \left(\frac{W_2}{W_1} d - 1 \right) + 0.000026 \, (t' - t°) \left(\frac{W_2}{W_1} d \right)$$

$$S_{vac} = \frac{W_2}{W_1} - 0.0012 \left(\frac{W_2}{W_1} - 1 \right) + 0.000026 (t' - t°) \left(\frac{W_2}{W_1} \right)$$

Determinations made with a plummet or sinker.

The equations above may also be used when the density is determined with plummet or sinker, but in this case

W_1 = weight of the plummet in air minus its weight in water.

W_2 = weight of the plummet in air minus its weight in the liquid.

CONVERSION OF SPECIFIC GRAVITY AT 25°/25° C. TO DENSITY AT ANY TEMPERATURE FROM 0° TO 40° C.

Cf. Dreisbach, *Ind. Eng. Chem., Anal. Ed. 12, 160 (1940).*

Liquids change volume with change in temperature but the amount of this change, β (coefficient of cubical expansion), varies widely with different liquids, and to some extent for the same liquid at different temperatures. See special table, *Coefficients of Cubical Expansion for Various Liquids and Aqueous Solutions.*

The table below, which is calculated from the relationship:

$$F_{\beta t}=\frac{\textit{density of water at } 25°C.\ (=0.99705)}{[1-\beta\ (25-t)]} \quad (1)$$

may be used to find d^t, the density (weight of 1 cc.), of a liquid at any temperature (t) between 0° and 40°C. if the specific gravity at 25°/25°C. (S) and the coefficient of cubical expansion (β) are known. Substitutions are made in the equations:

$$d^t=SF_{\beta t} \quad (2)$$

$$S=\frac{d^t}{F_{\beta t}} \quad (3)$$

TABLE—FACTORS ($F_{\beta t}$)

Density t°C. = Sp. Gr. 25°/25° × $F_{\beta t}$

°C. / *$\beta\times10^3$	0	5	10	15	20	25	30	35	40

0.4	1.0071	1.0051	1.0031	1.0011	0.99908	0.99705	0.9951	0.9931	0.9911

* β = coefficient of cubical expansion.

EXAMPLES

All examples are based upon an assumed coefficient of cubical expansion, β, of 1.3×10^{-3}.

Example 1. To find the density of a liquid at 20°C., d^{20}, which has a specific gravity (S) of $1.2500\frac{20°}{25°}$.

From the table above $F_{\beta t}$ at 20°C. = 1.0036.

$$d^{20}=d^t=SF_{\beta t}=1.2500\times1.0036=1.2545$$

CONVERSIONS OF DENSITY—SPECIFIC GRAVITY

Example 2. To find the density at 20°C. (d^{20}) of a liquid which has a specific gravity of $1.2500^{17^\circ}_{4^\circ}$.

Since the density of water at 4°C. is equal to 1, specific gravity at $17°/4° = d^{17} = 1.2500$.

Substitution in equation *3* with $F\beta_t$ at 17°C., by interpolation from the table, equal to 1.00756, gives

$$Sp.\ gr.\ 25°/25° = S = 1.2500 \div 1.00756$$

Substitution of this value for S in equation *2* with $F\beta_t$ at 20°C., from the table, equal to 1.0036, gives

$$d^{20} = d^t = (1.2500 \div 1.00756) \times 1.0036 = 1.2451$$

Example 3. To find the specific gravity at 20°/4°C. of a liquid which has a specific gravity of $1.2500^{25^\circ}_{4^\circ}$.

Since the density of water at 4°C. is equal to 1, specific gravity $25°/4° = d^{25} = 1.2500$; and, specific gravity $20°/4° = d^{20}$.

Substitution in equation *3*, with $d^t = 1.2500$; and, with $F\beta_t$ at 25°C., from the table, equal to 0.99705, gives

$$Sp.\ gr.\ 25°/25° = S = 1.2500 \div 0.99705$$

Substitution of this value for S in equation *2*, with $F\beta_t$ at 20°C., from the table, equal to 1.0036, gives

$$Sp.\ gr.\ 20°/4° = d^{20} = (1.2500 \div 0.99705) \times 1.0036 = 1.2582$$

Example 4. To find the density at 25°C. of a liquid which has a specific gravity of $1.2500^{25^\circ}_{15^\circ}$.

Since the density of water (see special table, *Absolute Density of Water*) at 15°C. = 0.99910,

$$d^{15} = sp.\ gr.\ 15°/15° \times 0.99910 = 1.2500 \times 0.99910$$

Substitution in equation *3*, with $F\beta_t$ at 15°C., from the table, equal to 1.0102, gives

$$Sp.\ gr.\ 25°/25° = S = (1.2500 \times 0.99910) \div 1.0102$$

Substitution of this value for S in equation *2*, with $F\beta_t$ at 25°, from the table, equal to 0.99705, gives

$$d^{25} = d^t = (1.2500 \times 0.99910 \div 1.0102) \times 0.99705 = 1.2326$$

DENSITY OF AQUEOUS SOLUTIONS

The values in the following tables have been computed from the values given under *specific gravity* and *per cent by weight* by means of the following factors:

$$\text{Degrees Baumé} = 145 - \frac{145}{\text{Sp. gravity}}$$

Degrees Twaddell = (Sp. gravity -1)$\times 200$
Grams per Liter = Sp. gravity $\times$ per cent by weight $\times$ 10
Pounds per U. S. Gallon = Grams per Liter $\times$ 0.0083454
Pounds per Cubic Foot = Grams per Liter $\times$ 0.06243

See also the tables:—"*Specific Gravity of Aqueous Solutions*", "*Specific Gravity of Alcohol Water Solutions*," and "*Hydrometer Conversion Tables.*"

ACETIC ACID

Density of Aqueous Acetic Acid Solutions at $\frac{20°}{4°}$ C. Computed from Values Given in the International Critical Tables.

AMMONIA

Specific Gravity of Aqueous Ammonia Solutions.

Adopted 1903 as Standard by the Manufacturing Chemists' Association of the United States.

Authority: W. C. Ferguson.

Specific Gravity determinations were made at 60°F., compared with water at 60°F.

From the Specific Gravities the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = \frac{140}{\text{Sp. Gr.}} - 130.$$

* Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

Atomic weights from F. W. Clarke's table of 1901. O = 16.

HYDROCHLORIC ACID

Specific Gravity of Aqueous Hydrochloric Acid Solutions. Adopted 1903 as Standard by the Manufacturing Chemists' Association of the United States.

Authority: W. C. Ferguson.

Specific Gravity determinations were made at 60° F., compared with water at 60°F. From the Specific Gravities, the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = 145 - \frac{145}{\text{Sp. Gr.}}$$

* Baumé Hydrometers for use with this table must be graduated by the above formula which formula should always be printed on the scale.

Atomic weights from F. W. Clarke's table of 1901. O = 16.

ALLOWANCE FOR TEMPERATURE:

10 — 15° Be. — 1/40° Be. or .0002 Sp. Gr. for 1° F.
15 — 22° Be. — 1/30° Be. or .0003 Sp. Gr. for 1° F.
22 — 25° Be. — 1/28° Be. or .00035 Sp. Gr. for 1° F.

NITRIC ACID

Specific Gravity of Aqueous Nitric Acid Solutions. Adopted 1903 as Standard by the Manufacturing Chemists' Association of the United States. Authority: W. C. Ferguson.

Specific Gravity determinations were made at 60°F., compared with water at 60°F. From the Specific Gravities, the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} \quad 145 - \frac{145}{\text{Sp. Gr.}}$$

Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

Atomic weight from F. W. Clarke's table of 1901. O = 16.

ALLOWANCE FOR TEMPERATURE:

At 10° — 20° Be. — 1/30° Be. or .00029 Sp. Gr. = 1°F.
20° — 30° Be. — 1/23° Be. or .00044 Sp. Gr. = 1°F.
30° — 40° Be. — 1/20° Be. or .00060 Sp. Gr. = 1°F.
40° — 48.5° Be. — 1/17° Be. or .00084 Sp. Gr. = 1°F.

SULFURIC ACID

Specific Gravity of Aqueous Sulfuric Acid Solutions Adopted 1904 as Standard by the Manufacturing Chemists' Association of the United States.

Authorities: W. C. Ferguson; H. P. Talbot.

Specific Gravity determinations were made at 60°F., compared with water at 60°F. From the Specific Gravities, the corresponding degrees Baumé were calculated by the following formula:

$$\text{Baumé} = 145 - \frac{145}{\text{Sp. Gr.}}$$

Baumé Hydrometers for use with this table must be graduated by the above formula, which formula should always be printed on the scale.

66° Baumé = Sp. Gr. 1.8354.

1 cu. ft. water at 60°F. weighs 62.37 lbs. avoirdupois.

Atomic weights from F. W. Clarke's table of 1901. O = 16.

H_2SO_4 = 100 per cent

	H_2SO_4	O. V.	60°
O. V.	93.19	100.00	119.98
60°	77.67	83.35	100.00
50°	62.18	66.72	80.06

Acids stronger than 66° Bé should have their percentage compositions determined by chemical analysis.

* Calculated from Pickering's results, Journal of London Chemical Society, vol. 57, p. 363.

FUMING SULFURIC ACID

This table may be used in calculating the quantity of concentrated sulfuric acid to be added to an oleum to obtain an oil of any desired lower strength in free SO_3. Gerster (*Chem. Zeit.* 11, 3 (1887)) gives the following formula for this purpose: $x = 100(b - a)/(a - c)$, where x represents the quantity of sulfuric acid to be added to 100 parts of the oleum, a the total SO_3 per 100 parts of the acid desired, b the total SO_3 per 100 parts of the original strong oleum, and c the SO_3 per 100 parts of the acid used for dilution. The values for a and b are taken from the table; c is obtained by multiplying the percentage of H_2SO_4 present in the acid used for dilution by 0.816

ETHYL ALCOHOL

Specific gravity of aqueous solutions of ethyl alcohol at $\frac{15.56°}{15.56°}$ C. To convert to specific gravity at $\frac{15.56°}{4°}$ C, multiply the specific gravities as given in the table by 0.99908.

(U. S. Dept. of Agriculture.)

Specific gravity $\frac{15.56°C.}{15.56°C.}$	% Alcohol by volume	% Alcohol by weight	Grams Alcohol per 100 cc
1.00000	0.00	0.00	0.00
0.99984	0.10	0.08	0.08

METHYL ALCOHOL

Specific gravity of aqueous solutions of methyl alcohol at $\frac{15.6°}{15.6°}$ C. To convert to specific gravity at $\frac{15.6°}{4°}$ C, multiply the specific gravities as given in the table by 0.99908.

[Arkiv. Kemi Min. Geol. [2] 27, 32 (Stockholm.)]

IMMERSION REFRACTOMETER READINGS OF METHYL ALCOHOL AND ETHYL ALCOHOL AT 17.5°C.—DETERMINATION OF MIXTURES OF METHYL ALCOHOL AND ETHYL ALCOHOL IN AQUEOUS SOLUTION

The data in the table below are given in the *Official and Tentative Methods of Analysis*, 4th ed. (1935), p. 175; reprinted by permission of the Association of Official Agricultural Chemists, Washington, D. C.

The method for the determination of mixtures of these two alcohols is that of Leach and Lithgoe, *Jour. Amer. Chem. Soc.* 27, 964 (1905) as corrected by Williams, *Ind. Eng. Chem.* 19, 844 (1927).

Example.—To calculate the percentage of methyl and ethyl alcohols in an aqueous mixture, assuming a distillate with an immersion refractometer reading of 35.0 at 17.5°C. and a specific gravity of 0.9793 at 15.56°/15.56°C.

By reference to the table below, an aqueous solution of methyl alcohol of specific gravity 0.9793 at 15.56°/15.56°C. has an immersion reading of 23.2; an aqueous solution of ethyl alcohol of specific gravity 0.9793 at 15.56°/15 56°C. has an immersion reading of 39.4. The difference between these two values is: (39.4 − 23.2), or 16.2; therefore, (39.4 − 35.0) ÷ 16.2, or 27.2% of the alcohols present in the mixture is methyl alcohol.

By reference to tables showing the percentages of these alcohols corresponding to the various specific gravities, an aqueous methyl alcohol solution having a specific gravity of 0.9793 at 15.56°/15.56°C. contains 15.72% by volume of methyl alcohol. An aqueous solution of ethyl alcohol of the same specific gravity contains 16.80% by volume of ethyl alcohol. A distillate of this same specific gravity in which 27.2% of the alcohol is methyl alcohol and 72.8% is ethyl alcohol would contain: 16.80 − [(16.80 − 15.72) ÷ 27.2], or 16.76% by volume of total alcohols. Since 27.2% of this volume is methyl alcohol, 100 cc. of the solution contain 4.56 cc. of methyl alcohol and 12.20 cc. of ethyl alcohol. At 15.56°C., 1 cc. of methyl alcohol weighs 0.7958 g., and 1 cc. of ethyl alcohol weighs 0.7939 g. Therefore, 100 cc. of the distillate contain 4.56 × 0.7958, or 3.63 g. of methyl alcohol; and, 12.20 × 0.7939, or 9.69 g. of ethyl alcohol. As 100 cc. of the distillate weigh 97.93 g., the distillate contains: 3 63 ÷ 97.93, or 3.71% by weight of methyl alcohol; and, 9.69 ÷ 97.93, or 9.89% by weight of ethyl alcohol.

This shows that there is present:	By weight	By volume
Methyl alcohol :	3.71%	4.56%
Ethyl alcohol :	9.89%	12.20%

PROOF AND PERCENTAGE OF ETHYL ALCOHOL

U. S. Proof is double the alcoholic % by vol. at 60° F. Per cent of alcohol by wt. is approximately four-fifths of the % of alcohol by vol. British Proof is approximately 11 parts by vol. of alcohol and 10 parts by vol. of water. It is the equivalent of 114.2 U. S. Proof and has a sp. gr. of 0.9198 at 60° F., with 57.06% by vol. or 49.24% by wt. of absolute alcohol. British Proof has the following relationships between % by wt. (W), % by vol. (V), % proof spirit (P), and sp. gr. (D).

$$W = \frac{P}{D \times 2.208} \qquad V = \frac{W \times D}{0.7938} = W \times D \times 1.26 \qquad P = W \times D \times 2.208$$

$$W = \frac{V \times 0.7938}{D} \qquad V = P \times 0.5706 \qquad P = \frac{V}{0.5706} = V \times 1.7525$$

Butter	0.94–0.95	58.5–59.2
Calcspar	2.6–2.8	162–174
Caoutchouc	0.92–0.99	57.3–61.4
Cast iron	7.25	452
Celluloid	1.4	87
Cement	0.82–1.95	51–121
Chalk	1.8–2.6	112–162
Charcoal	0.4	25
Charcoal, air free	1.4–1.5	87–93
China, Chinese	2.38	148
China, French	2.24	140

Name	Grams per cc	Pounds per cu. ft.
China, German	2.29–2.49	143–155
Cinnabar	8.12	506
Clay	1.8–2.6	112–162
Clinker brick	1.7–2.0	106–125
Coal	1.2–1.5	75–93
Coal, pressed	1.25	77.9
Coke	1.4	87
Concrete	1.80–2.45	112–153
Copal	1.04–1.14	64.8–71.0
Cork	0.24	15
Corkboard, black	0.56	35
Corkboard, white	0.25	15.6
Cotton, air dried	1.47–1.50	91.6–93.5
Diamond	3.01–3.52	187.5–219
Earth, loamy, dry	1.6–1.9	100–118
Earth, loamy, pressed	2.0	125
Ebonite	1.15	71.6
Feldspar	3.25–3.50	202–218
Feldspar	2.5	156
Fire brick	1.85–2.2	115–137
Flax, air dried	1.5	93
Flint	2.6–2.8	162–174
Flour, loose	0.4–0.5	25–31
Flour, pressed	0.7–0.8	44–50

DENSITIES OF VARIOUS SOLIDS AND LIQUIDS (Continued)

Name	Grams per cc	Pounds per cu. ft.
Gamboge	1.2	75
Garnet	3.4–4.3	212–268
Gas carbon	1.88	117
Gasoline	0.66–0.69	41–43
Gelatine	1.27	79.1
Glass, crystal	2.9–3.0	181–187
Glass, flask	2.6	162
Glass, flint	3.15–3.90	196–243
Glass, mirror	2.45–2.72	153–169
Glass, window	2.4–2.6	150–162
Glue	1.27	79.1
Gneiss	2.4–2.7	150–168
Granite	2.51–3.05	156–190
Graphite	2.30–2.72	143–169
Gravel	1.8–2.0	112–125
Gum arabic	1.31–1.45	81.6–90.3
Gunpowder, loose	0.9	56
Gunpowder, pressed	1.75	109
Guttapercha	0.96–0.99	60–61.6
Gypsum, calcined	1.81	113
Gypsum, dry, moulded	0.97	60.4
Gypsum, sifted	1.25	77.9
Hemp, fiber, air dried	1.5	93
Ice	0.88–0.92	54.8–57.3
India rubber	0.91–0.93	56.7–57.9
Ivory	1.83–1.92	114–120
Kaolin	2.2–2.5	137–156
Lava, basaltic	2.8–3.0	174–187
Lava, trachitic	2.0–2.7	125–168
Leather	1.02	63.5
Leather, dried	0.86	53.6
Lignite	1.2–1.5	75–93
Lime mortar, dry	1.60–1.65	99.7–102.8
Lime mortar, fresh	1.75–1.80	109–112
Lime stone	2.46–2.84	153–177
Linoleum	1.15–1.3	71.6–81
Litharge, artificial	9.3–9.4	579–586
Litharge, natural	7.83–7.98	488–497
Loam, dried	1.5–1.6	93–100
Loam, fresh	1.67–1.85	104–115
Marble	2.52–2.85	157–177.5
Marl	2.3–2.5	143–156
Masonry brick, dry	1.42–1.46	88.5–91.0
Masonry brick, fresh	1.57–1.63	97.8–101.5
Meerschaum	0.99–1.28	61.7–79.7
Mica	2.65–3.2	165–199
Milk	1.028–1.035	64.04–64.48
Millstone quartz	1.25–1.60	77.9–99.7
Oats	0.43	26.8

Name	Grams per cc	Pounds per cu. ft.
Ocher	3.5	218
Opal	2.2	137
Paper	0.70–1.15	43.6–71.6
Paraffin	0.87–0.91	54.2–56.7
Peat	0.64	39.9

Pig iron, gray	6.7–7.6	417–473
Pig iron, white	7.0–7.8	436–486
Pitch	1.07–1.10	66.7–68.5
Pitch peat	0.84	52.5
Polishing slate	2.1	131
Porcelain clay	2.2	137
Porphyry	2.4–2.8	150–174
Potato	1.06–1.13	66.0–70.4
Pumice	0.37–0.9	23–56
Quicklime	2.3–3.2	143–199
Red lead	8.6–9.1	536–567
Rock salt	2.28–2.41	143–150
Rosin	1.07	66.7
Rubber fabric	1.0–2.0	62.3–125
Rubber, gum	0.92–0.96	57.3–59.8
Rubber, raw	0.92–0.96	57.3–59.8
Rye	0.68–0.79	42.4–49.2
Sand, coarse	1.4–1.5	87–93.5
Sand, fine, dry	1.40–1.65	87.2–102.8
Sand, fine, moist	1.90–2.05	118.4–127.7
Sandstone	2.2–2.5	137–156
Sandstone, artificial	2.0–2.1	125–131
Sea water	1.025	63.86
Siderite	3.7–3.9	231–243
Silica	2.66	166
Silk, raw	1.56	97.2
Slag, blast furnace	2.5–3.0	156–187
Slaked lime	1.15–1.25	69.6–77.9
Slate	2.65–2.70	165–168
Snow, loose	0.125	7.79
Soapstone	2.7	168
Starch, lumps	1.53–1.56	95.3–97.2
Steel, ingot	7.87	490
Sugar, white	1.61	100.3
Tallow	0.90–0.97	56.1–60.4
Tar	1.02	63.6
Tufa, lump	1.3	81
Tufa, tile	0.8–0.9	50–56
Verdigris	1.9	118
Wax, sealing	1.8	112
Wheat	0.7–0.8	44–50
White lead	6.7	417
Wood	0.31–1.33	19.3–82.9
Wood naphtha	0.810–0.848	50.5–52.9
Wool, air dried	1.32	82.2

RELATIVE DENSITY AND VOLUME OF WATER* AND OF MERCURY AT VARIOUS TEMPERATURES

These values are based upon the mass of one milliliter of water at 4°C. as unity. To convert to absolute density in C. G. S. units multiply the value for relative density by 0.999973.

WATER			MERCURY		
Temp. Degree C.	Relative Density g/ml	Volume ml/g	Relative Density g/ml	Volume ml/g	Temp. Degree C.

FREEZING MIXTURES

The table below gives the percent of the anhydrous material as shown in the column on the left in the eutectic mixture with ice. The eutectic temperature is the lowest temperature which can be obtained from a mixture of the substance with ice. To obtain the maximum cooling effect, the freezing mixture should be prepared with ice rather than with water and the other ingredient should be cooled to 0°C. For most purposes sodium chloride and ice, or calcium chloride and ice, mixtures are most common providing temperatures of -21.2°C. and -55°C. respectively.

Formula of Substance	%	Eutectic Temp. °C.
$BaCl_2$	22.5	−7.8
$CaCl_2$	29.8	−55
$Ca(NO_3)_2$	35	−16
$CuCl_2$	36	−40
$Cu(NO_3)_2$	36	−24
$CuSO_4$	11.9	−1.6
$FeCl_3$	33.1	−55
$FeSO_4$	13.04	−1.824
HCl	24.8	−86
HNO_3	32.7	−43
K_2CO_3	39.5	−36.5
KCl	19.75	−11.1
K_2CrO_4	36.6	−11.3
KOH	31.5	−65
KNO_3	10.9	−2.9
$MgCl_2$	21.6	−33.6
$Mg(NO_3)_2$	34.6	−29
$MgSO_4$	19	−3.9
$MnSO_4$	32.2	−10.5
NH_4Cl	18.6	−15.8
NH_4NO_3	41.2	−17.35
$(NH_4)_2SO_4$	38.3	−19.05
NaBr	40.3	−28
Na_2CO_3	5.9	−2.1
NaCl	23.3	−21.13
NaOH	19	−28
$NaNO_3$	37	−18.5
Na_2SO_4	12.7	−3.55
$Na_2S_2O_3$	30	−11
$NiSO_4$	20.6	−4.15
SO_3	32	−75
$SrCl_2$	26	−18.7
$Sr(NO_3)_2$	24.5	−5.75
$ZnCl_2$	51	−62
$Zn(NO_3)_2$	39.4	−29
$ZnSO_4$	27.2	−6.55

NON-AQUEOUS COOLING BATHS

Low temperatures may be produced by mixtures of various substances with carbon dioxide snow or by evaporation of low boiling liquids.*

Substance	Deg. C.
Alcohol-carbon dioxide	−72
Ammonia, boiling point	−33.4
Chloroform-carbon dioxide	−77
Ether-carbon dioxide	*ca* −78
Ethyl chloride, boiling point	+12.5
Liquid air, boiling point	−190
Nitrogen, boiling point	−196
Oxygen, boiling point	−183
Sulfur dioxide, boiling point	−10

* The assertion that certain baths with CO_2 snow, especially the acetone bath, give a temperature materially lower than pure dry CO_2 snow is erroneous. Cf. Thiel and Caspar, *Z. physik. Chem.* **86**, *257–93 (1914)*; *C. A.* **8**, *1229 (1914)*. Liquid nitrogen (but not liquid air, which is hazardous) poured into ethyl alcohol until a slush is formed gives a cooling bath −115° to −125°C.

According to Kolb, *Chemist-Analyst*, 1-methoxy-2-propanol is a very good liquid for dry ice cooling baths. This solvent is available from the Dow Chemical Co., Midland, Mich., under the trade name DOWANOL 33-B.

† Values are for pure alcohol. Since some commercial antifreezes contain small amounts of water, slightly higher volume concentrations than those given in the table may be required. Antifreezes also contain corrosion inhibitors and other additives to make them function properly as cooling liquids. These affect freezing point slightly and specific gravity to a greater degree. If a protection table is furnished by the manufacturer it should be used in preference to the values given above for the pure substance.

* Eveready Prestone (manufactured by the National Carbon Co.), marketed for antifreeze purposes, is 97% ethylene glycol containing fractional percentages of soluble and insoluble ingredients to prevent foaming, creepage and water corrosion in automobile cooling systems.

PROPYLENE GLYCOL-GLYCEROL

Propylene glycol, a satisfactory antifreeze with the advantage of being non-toxic, can be combined with glycerol, also an efficient non-toxic antifreeze, to give a mixture that can be tested for freezing point with an ethylene glycol (Prestone) hydrometer. A mixture of 70% propylene glycol and 30% glycerol (% by weight of water-free materials), when diluted, can be tested on the standard instrument used for ethylene glycol solutions.

*Trade names for dichlorodifluoromethane, trichloromonofluoromethane, dichloromonofluoromethane, and dichlorotetrafluoroethane.

Note X—Carbon Dioxide not a liquid at atmospheric pressure.

Note Y—Density of gas at 0°C. (32°F.) and 760 mm. (1 atm.), except for Ethyl Chloride for which no temperature has been given.

MOLECULAR DEPRESSION OF THE FREEZING POINT

The constant K_F gives the depression of the freezing point in °C. produced by solution of one gram molecular weight of a substance in 1000 grams of any one of the solvents listed below.

Compound	Freezing Point °C.	K_F	Heat of Fusion gram-cal. per gram
Acetic acid	16.7	3.9	43.2
Aluminum bromide	97.5	26.8	10.47
Barium chloride	962	108	27.8
Benzene	5.5	5.12	30.1
Benzophenone	48.5	9.8	23.5
Bromoform	7.8	14.4	10.9
Camphor*	178.4	37.7	10.74
Cyclohexane	6.5	20.0	7.4
m-Dinitrobenzene	89.8	10.6	24.7
1, 4-Dioxane	10.5	4.9	.....
Diphenyl	70.0	8.0	28.8
Diphenylamine	52.9	8.6	25.2
Ethylene bromide	9.98	12.5	13.5
Formamide	2	3.8	...
Formic acid	8.6	2.77	58.9
Naphthalene	80.2	6.9	36.0

Compound	Freezing Point °C.	K_F	Heat of Fusion gram-cal. per gram
β-Naphthol	122.5	11.25	31.3
Nitrobenzene	5.7	8.1	22.46
Phenanthrene	99.3	12.0	25.0
Phenol	42	7.27	29.0
Salol	43	12.3	16.13
Stannic bromide	31	28.0	6.49
Stearic acid	69	4.5	47.6
Strontium chloride	873	107	25.6
Sulfuric acid	10.5	6.81	24.03
p-Toluidine	44.5	5.2	39.9
Tribromophenol	96	20.4	13.4
Triphenyl methane	93	12.45	21.1
Triphenyl phosphate	49.9	11.76	17.56
Urethane	49.7	5.14	40.9
Water	0	1.86	79.67
p-Xylene	13.2	4.3	38.1

* A K_F of 40 is better. According to Rast (*Ber.* 55, 1051, 3727 (1922) mol. wt. determinations may be made with an ordinary thermometer.

MOLECULAR ELEVATION OF THE BOILING POINT

The constant K_B gives the elevation of the boiling point in °C. produced by solution of one gram molecular weight of a substance in 1000 grams of any one of the solvents listed below. In the column headed *Barometric Correction* is given the number of degrees for each mm. of difference between the barometric reading and 760 mm. of mercury to be subtracted from K_B if the pressure is lower, or added if higher, than 760 mm. Cf. Hoyt and Fink, *J. Phys. Chem.* 41, 453 (1937).

Compound	Boiling Point °C.	K_B	Barometric Correction per mm. Hg	Heat of Vaporization gram-cal. per gram.

IONIZATION CONSTANTS OF ACIDS AND BASES AT 25° C.

Figures in italics are activity constants (ionic strength zero).

Values in the table have been collected from various sources including among others:

Kolthoff and Stenger: *Volumetric Analysis*, 2d ed. 1942, Vol. I, Table II, Published by Interscience Publishers, New York, by permission of the publishers.

Mac Innes: *Principles of Electrochemistry* (1939), Table VIII, Published by Reinhold Publishing Corp., New York, by permission of the publishers.

Dippy: *Chem. Reviews* **25**, *203-11 (1939)*.

o-Phenylenediamine	$(H_2N)_2C_6H_4$		3.3×10^{-10}	9.48
p-Phenylenediamine	$(H_2N)_2C_6H_4$	K_1	1.1×10^{-8}	7.96
		K_2	3.5×10^{-12}	11.46
β-Phenylethylamine	$NH_2\cdot C_8H_9$		6.75×10^{-5}	4.17
β-Phenylethyl-methylamine	$CH_3NH\cdot C_8H_9$		1.39×10^{-4}	3.86
Phenylhydrazine	$C_6H_5NH\cdot NH_2$	(40°)	1.6×10^{-9}	8.80
γ-Phenylpropylamine	$NH_2\cdot C_9H_{11}$		2.48×10^{-4}	3.61
N, N-iso-Propylbenzylamine	$C_3H_7NH\cdot C_7H_7$		4.18×10^{-5}	4.38
Physostigmine	$C_{15}H_{21}O_2N_3$	K_1	7.6×10^{-7}	6.12
		K_2	5.7×10^{-13}	12.24
Pilocarpine	$C_{11}H_{16}O_2N_2$	K_1	7×10^{-8}	7.15
		K_2	2×10^{-13}	12.7
Piperazine	$C_4H_{10}N_2$	K_1	6.4×10^{-5}	4.19
		K_2	3.7×10^{-9}	8.43
Piperidine	$C_5H_{11}N$		1.6×10^{-3}	2.80
Piperine	$C_{17}H_{19}O_3N$		1.0×10^{-14}	14.0
n-Propylamine	$C_3H_7NH_2$		3.9×10^{-4}	3.41
iso-Propylamine	$C_3H_7NH_2$		4.3×10^{-4}	3.37
Propyl cyanide	C_3H_7CN		1.8×10^{-15}	14.74
Pyridine	C_5H_5N		1.4×10^{-9}	8.85
Quinidine	$C_{20}H_{24}O_2N_2$	K_1	3.5×10^{-6}	5.46
		K_2	1×10^{-10}	10.0
Quinine	$C_{20}H_{20}O_2N_2$	K_1	1×10^{-6}	6.0
		K_2	1.3×10^{-10}	9.89
Quinoline	C_9H_7N		6.3×10^{-10}	9.20
Sarcosine	$CH_3NH\cdot C_2H_3O_2$		1.02×10^{-4}	3.99
Semicarbazide	$H_2N\cdot CH_3ON_2$	(40°)	2.7×10^{-11}	10.57
Silver hydroxide	$AgOH$		1.1×10^{-4}	3.96
Solanine	$C_{44}H_{71}O_{15}N$		2.2×10^{-7}	6.66
Sparteine	$C_{15}H_{26}N_2$	K_1	5.7×10^{-3}	2.24
		K_2	1×10^{-6}	6.0
Strychnine	$C_{21}H_{22}O_2N_2$	K_1	1×10^{-6}	6.0
		K_2	2×10^{-12}	11.7
Tetramethylenediamine	$(NH_2)_2C_4H_8$		4.1×10^{-4}	3.39
Thebaine	$C_{19}H_{21}O_3N$		9×10^{-7}	6.05
Theobromine	$C_7H_8O_2N_4$	(40°)	4.8×10^{-14}	13.32
Thiazole	C_3H_3NS		3.3×10^{-12}	11.48
Thiourea	CH_4N_2S		1.1×10^{-15}	14.96
o-Toluidine	$H_2N\cdot C_7H_7$		3.3×10^{-10}	9.48
m-Toluidine	$H_2N\cdot C_7H_7$		5.5×10^{-10}	9.26
p-Toluidine	$H_2N\cdot C_7H_7$		2×10^{-9}	8.70
Tri-*iso*-butylamine	$(C_4H_9)_3N$		2.1×10^{-4}	3.68
Triethylamine	$(C_2H_5)_3N$		5.65×10^{-4}	3.25
Trimethylamine	$(CH_3)_3N$		5.27×10^{-5}	4.28
Trimethylenediamine	$(NH_2)_2C_3H_6$		2.8×10^{-4}	3.55
Tripropylamine	$(C_3H_7)_3N$		5×10^{-4}	3.30
Urea	CH_4ON_2		1.5×10^{-14}	13.82
Veratrine	$C_{32}H_{49}O_9N$		7×10^{-6}	5.15
Xanthine	$C_5H_4O_2N_4$	(40°)	4.8×10^{-14}	13.32
Zinc hydroxide	$Zn(OH)_2$	K_2	4.4×10^{-5}	4.36

ACTIVITY COEFFICIENTS OF IONS IN WATER AT 25°C

Values in the following table by Kielland (*J. Am. Chem. Soc.*, 59, 1675; 1937) were calculated by means of one form of the Debye-Hückel equation.

Inorganic ions	Total ionic concentration in moles per liter							
	0.001	0.002	0.005	0.01	0.02	0.05	0.1	0.2
H^+	0.975	0.967	0.950	0.933	0.914	0.88	0.86	0.83

ELECTRICAL CONDUCTIVITY OF AQUEOUS SOLUTIONS

In the table below are given values for the conductivity and the equivalent conductivity of various aqueous solutions. The percent by weight is that of the anhydrous substance. The conductivity in mhos/cm. divided by the conductivity in gram-equivalents per cubic centimeter is the equivalent conductivity.

Formula	Temp. °C.	% by Weight	Cond. mho/cm ×10⁴	Equiv. Cond.
$AgNO_3$	18	5	256	83.4
		10	476	74.3

ELECTRICAL CONDUCTIVITY OF STANDARD SOLUTIONS

In the table below, the normal KCl solution was prepared by dissolving 74.59g of KCl in water and diluting to one liter at 18°C. The specific gravity of such a solution is 1.0449 at 18°C.

The concentrations of H_2SO_4 and of $MgSO_4$ are those of maximum conductivity at 18°C.

The NaCl solution is saturated at all the temperatures given, and has a specific gravity of 1.2014 at 18°C.

	Conductivity in mhos/centimeter, or $ohm^{-1}cm^{-1}$.

SINGLE ELECTRODE POTENTIALS AT 25°C

It is convenient to consider that the total emf of a cell is the sum of two "single electrode potentials." That is,

$$(1)\quad E_{cell} = E_{ox} + E_{red}$$

Where E_{ox} is the single electrode potential of the electrode forming the negative pole of the cell, and E_{red} is the single electrode potential of the electrode forming the positive pole of the cell. An oxidation process always occurs at the negative pole of a primary cell, while a reduction process occurs at the positive pole. If a particular substance is more easily oxidized than hydrogen, its E_{ox} is assigned a positive value and its E_{red} a negative value. If a substance is not oxidized as easily as hydrogen, its E_{ox} is negative and E_{red} is positive in sign.

The values given in the table below are $E°_{red}$ values, where $E°$ is the single electrode potential when each substance involved in the electrode reaction is at unit "activity." Values of $E°_{ox}$ may be obtained merely by changing the sign of the $E°_{red}$ values.

If the half reaction involves H^+ as product or reactant, the solution is acid. Half reactions involving OH^-, NH_3, CN^-, CO_3^{--}, or S^{--} are reactions occurring in an alkaline solution.

Not all of the $E°$ values in this table were determined by emf measurements. Some were calculated from free energy data. For details, see Latimer, "The Oxidation States of the Elements," Prentice-Hall, Inc., New York, 1938.

One substance on the left side of each half reaction is an oxidizing agent, and one substance on the right side of each half reaction is a reducing agent. As one proceeds downward in the table the oxidizing agents increase in strength, and the reducing agents decrease in strength. In general, if two half reactions are represented by the following equations:

$$\text{ox. agent}_1 + ne = \text{red. agent}_1$$
$$\text{ox. agent}_2 + ne = \text{red. agent}_2$$

and the second equation occurs lower in the table than the first equation, then a reaction may occur between ox. agent_2 and red. agent_1, whereas no reaction is possible between ox. agent_1 and red. agent_2. For example, considering the half reactions:

$$I_2 + 2e = 2I^- \quad (E°_{red} = 0.535 \text{ volt})$$
$$Cu^{++} + I^- + e = CuI \quad (E°_{red} = 0.877 \text{ volt})$$

from the rule, Cu^{++} should react with I^-, and no reaction should occur between I_2 and CuI.

To obtain the overall reaction between two half reactions, the half reaction which is higher in the table is reversed. Each equation is multiplied through by the proper numbers so that the number of electrons lost in the reversed upper equation is equal to the number of electrons gained in the lower half reaction. The two half-reactions are then added. For the reaction between Cu^{++} and I^- the overall reaction is obtained as follows:

$$2I^- = I_2 + 2e \quad \text{(upper half reaction reversed)}$$
$$2Cu^{++} + 2I^- + 2e = 2CuI \quad \text{(reaction multiplied by two)}$$
$$\overline{2Cu^{++} + 4I^- = I_2 + 2CuI} \quad \text{(overall reaction)}$$

If two or more reactions between two substances are possible, usually the reaction involving half reactions which are farthest apart in the table will occur first.

To calculate the single electrode potential, E_{red}, when the concentration of ions involved in the electrode reaction is other than unit activity, the following equation is used:

$$(2)\quad E_{red} = E°_{red} - \frac{0.000198322T}{n} \log_{10} \frac{(a_p)^a}{(a_r)^b}$$

where n number of electrons (e) involved in the half reaction; a_p activity of products, a_r activity of reactants; and, a and b are the coefficients of products and reactants, respectively, in the half reaction *written as a reduction reaction;* T is the absolute temperature; the value of $0.000198322T$ at 25° C is 0.05912.

SINGLE ELECTRODE POTENTIALS AT 25°C

Examples

For the cell: $^{(-)}Zn, Zn^{++}(a = 1) \parallel Cu^{++}(a = 1), Cu, ^{(+)}$

$E^\circ_{red} = -0.761$ or $E^\circ_{red} = 0.344$

$E^\circ_{ox} = 0.761$

$E_{cell} = E^\circ_{ox} + E^\circ_{red} = 0.761 + 0.344 = 1.105$ volts.

To calculate the emf and overall cell reaction for the cell:

$^{(-)}(Pt)Sn^{++}(a = 0.2), Sn^{++++}(a = 0.8) \parallel Mn^{++}(a = 0.3), MnO_4^-(a = 0.9)(Pt), H^+(a = 0.5)^{(+)}$

$E^\circ_{red} = 0.14$ or $E^\circ_{red} = 1.52$

$E^\circ_{ox} = -0.14$

The upper half of the two reactions, involving Sn, is reversed to give the oxidation half reaction

$$Sn^{++} = Sn^{++++} + 2e$$

$$E_{ox} = -0.14 - \frac{0.05912}{2} \log_{10} \frac{0.8}{0.2} = -0.14 - 0.018 = -0.158$$

The MnO_4^- half reaction is written as a reduction reaction:

$$MnO_4^- + 8H + 5e = Mn^{++} + 4H_2O$$

$$E_{red} = 1.52 - \frac{0.05912}{5} \log_{10} \frac{(0.3)}{(0.9)(0.5)^8} = 1.52 - 0.023 = 1.497$$

$E_{cell} = E_{ox} + E_{red} = 0.158 + 1.497 = 1.339$ volts

$5Sn^{++} = 5Sn^{++++} + 10e$ (oxidn. reaction multiplied by 5)

$2MnO_4^- + 16H^+ + 10e = 2Mn^{++} + 8H_2O$ (red. reaction multiplied by 2)

$5Sn^{++} + 2MnO_4^- + 16H^+ = 5Sn^{++++} + 2Mn^{++} + 8H_2O$ (complete reaction)

ELECTROMOTIVE SERIES OF THE METALS

Lithium	Sodium	Chromium	Lead	Mercury (ous)
Rubidium	Magnesium	Iron	HYDROGEN	Silver
Potassium	Beryllium	Cadmium	Antimony	Palladium
Barium	Aluminum	Cobalt	Arsenic	Mercury (ic)
Strontium	Manganese	Nickel	Bismuth	Platinum
Calcium	Zinc	Tin	Copper	Gold

AN ELECTROMOTIVE SERIES OF METALS AND ALLOYS

In general, when two metals are connected to each other and are immersed in sea water, or other salt solutions which are not too acid or alkaline, there will be a small or not appreciable action if the two metals are in the same group as given in the table below. If one metal is in one group and the other metal is in a different group, the metal in the group coming *first* in the table will be anodic to (*i.e.*, corroded by) the metal in the group coming later in the table. Thus, Aluminum 38 would probably be corroded by contact with lead or tin. For details, *cf.* La Que and Cox, *Proc. Amer. Soc. for Testing Materials*, **40**, *17* (*1940*).

COMPOSITION AND emf OF VOLTAIC CELLS

Compiled in collaboration with George W. Heise

Single-Fluid Cells

Name of cell	emf volts	Anode*	Electrolyte	Cathode
Air depolarized:				
Alkaline wet type	1.46	Amalg. zinc	20% NaOH	Carbon
Alkaline dry type	1.37	Zinc	25% NaOH + $Na_2Zn_2O_3$	Special carbon
Leclanche type	1.4±	Amalg. zinc	$NH_4Cl + ZnCl_2$	Carbon
Drumm (storage)	1.86	Zinc	$KOH + K_2Zn_2O_3$	Nickel oxide
Edison (storage)	1.5	Iron	21% KOH + 5% LiOH	Nickel oxide + nickel (or graphite)
Cadmium (storage)	1.35	Cadmium	KOH + LiOH	Nickel oxide
Lalande-Chaperon (Edison-Lalande)	0.95	Amalg. zinc	20% NaOH	CuO
Lead storage battery	2.1	Lead	H_2SO_4	PbO_2
Leclanche:				
Wet cell	1.5	Amalg. zinc	Sat'd. NH_4Cl	$C + MnO_2$
Dry cell	1.6	Amalg. zinc	$NH_4Cl + ZnCl_2$	$C + MnO_2$
Main (Reynier) (primary or storage)	2.5	Amalg. zinc	H_2SO_4	PbO_2
Magnesium (reserve type)	1.8	Magnesium	$MgCl_2$ †	AgCl
Mercuric oxide	1.35	Amalg. zinc	$KOH + K_2Zn_2O_3$	$HgO + C$
Perchloric acid	2.31	Lead	$HClO_4$	PbO_2
Poggendorf (Bunsen)	2.0	Amalg. zinc	12 parts $K_2Cr_2O_7$ + 25 parts H_2SO_4 + 100 parts H_2O	Carbon
Silver chloride	1.02	Amalg. zinc	NH_4Cl	Ag + AgCl
Volta	0.98	Zinc	NaCl	Ag (or Cu)

Two-Fluid Cells

Name of cell	emf volts	Anode	Anolyte	Catholyte	Cathode
Bunsen (modified Grove)	1.9±	Zinc	H_2SO_4	HNO_3	Carbon
Clark (standard cell)	1.4328 at 15°C	Zinc amalg.	$ZnSO_4$	Hg_2SO_4	Hg
Daniell	1.08±	Zinc	$ZnSO_4$ or $MgSO_4$	$CuSO_4$	Cu
Fuller	2.0	Amalg zinc	H_2SO_4	$K_2Cr_2O_7 + H_2SO_4$	C
Grove	1.93	Amalg. zinc	H_2SO_4	HNO_3	Pt
Weston (standard)	1.01827 at 20°C	Cd amalg.	$CdSO_4$	Hg_2SO_4	Hg

* For all except the original Volta pile (1800) zinc anodes may be considered as being amalgamated.

† Activated by addition of water; $MgCl_2$ formed during discharge: $Mg + 2AgCl = MgCl_2 + 2Ag$.

DIELECTRIC CONSTANTS

The dielectric constant (ϵ) of a material, sometimes called the specific inductive capacity, is a measure of the ratio of electric displacement to electric field intensity. The dielectric constant of a vacuum is unity.

GASES

Recommended Values of Reference Gases at 20°C and 1 Atmosphere

Maryott and Buckley, *Natl. Bur. Standards, Cir. 537 (1953)*.

The values of the dielectric constant (ϵ) can be adjusted to somewhat different conditions of temperature and pressure by means of the equation

$$\frac{(\epsilon - 1)_{t,p}}{(\epsilon - 1)_{20°,1atm}} = \frac{p}{760[1 + 0.003411(t - 20)]}$$

where p is the pressure in millimeters of mercury, and t is the temperature in degrees C. The errors associated with this equation probably do not exceed 0.1% for CO_2 and 0.02% for the remaining gases at temperatures between 10° and 30° and pressures between 700 and 800 mm.

Gas	ϵ	Gas	ϵ
He	1.0000650 ± 4	Ar	1.0005172 ± 4
H_2	1.0002538 ± 3	N_2	1.0005480 ± 5
O_2	1.0004947 ± 2	CO_2	1.000922 ± 1
		Air (dry, CO_2 free)	1.0005364 ± 3

In the following table the values are from various sources. The frequency in cycles per second is given in the column headed f.

Gas	t °C	f	ϵ	Gas	t °C	f	ϵ
Acetaldehyde	20	<3¶	1.0213	*n*-Heptane	100	<3¶	1.0035

DIELECTRIC CONSTANTS (Continued)

LIQUIDS

Recommended Values of Reference Liquids at 25°C

Maryott and Smith, *Natl. Bur. Standards, Cir. 514 (1951)*.

The values of a or α may be used for interpolating or for extrapolating over a limited range of termperature by means of the equations

$$\epsilon_{t'} = \epsilon_t - a(t' - t) \quad (1)$$

$$\text{Log}_{10}\ \epsilon_{t'} = \text{Log}_{10}\ \epsilon_t - \alpha\ (t' - t) \quad (2)$$

Liquid	ϵ	a or (α)	Liquid	ϵ	a or (α)
Benzene	2.274	0.0020	Hydrogen	1.228*	0.0034
Carbon tetrachloride	2.228	0.0020	Methanol	32.63	0.00260 (α)
Chlorobenzene	5.621	0.00133 (α)	Nitrobenzene	34.82	0.00225 (α)
Cyclohexane	2.015	0.0016	Oxygen	1.507†	0.0024
Ethylene chloride	10.36	0.00240 (α)	Water	78.54‡	0.00200 (α)

* At 20 4°K. † At 80.0°K.
‡ $\epsilon = 78.54[1 - 4.579(10^{-3})(t - 25) + 1.19(10^{-5})(t - 25)^2 - 2.8(10^{-8})(t - 25)^3]$; av. dev. ± 0.03%.

All of the substances and the values given in the following table, with the exception of those entered as "Oils," have been selected from a very comprehensive list in the Natl. Bur. of Standards' Cir. 514. Abbreviations: t, temp. °C; T, temp. °K; (t_1; t_2), the limits (range) of temperature between which a (or α) is considered applicable for use in equations *1* or *2* given above; f, frequency in cycles per second; the temperature of measurement is given in parentheses after the name.

SOLIDS

The frequency in cycles per second is given in the column headed *f*. The symbol *A* stands for "audio frequency" and signifies that the condenser frequency lies between 20 and 20,000 vibrations or cycles per second and is audible to the average person. Values for the dielectric constant (ϵ) in the following table are at ordinary room temperatures (17 to 22° C) unless otherwise given after the name of the solid. The symbols $\perp$ and $\parallel$ signify that the determinations were made perpendicular and parallel respectively to the optical axes in the case of crystals, and to the fibers in the case of woods. The word "mean" in parentheses following the name shows that the mean value of the three different axes in monoclinic and rhombic crystals is given.

DIPOLE MOMENTS OF VARIOUS SUBSTANCES

In this table and in the following table of *GROUP MOMENTS* the dipole moments are expressed in Debye units, usually represented by the symbol λ, which are equal to 10^{-18} electrostatic units. A dipole consists of two equal electrical charges, very close together and opposite in sign. Its magnitude is measured by its moment which is the product of either charge by the distance between the two charges.

Substance	λ	Substance	λ
Acetone	2.7	Diphenyl ether	1.15
Ammonia	1.46	Hydrazine	1.19
iso-Amyl cyanide	3.53	Hydrogen	0

Cyclohexane	0	Stannic iodide	0
o-Dichlorobenzene	2.51	Sulfur dioxide	1.6
Dioxane	0	Water	1.84

GROUP MOMENTS

The following data are taken by permission of the Publishers from "Dipole Moments" by C. P. Smyth in *PHYSICAL METHODS OF ORGANIC CHEMISTRY*, A. Weissberger, ed.; copyright, Interscience Publishers, New York (1946). For further information concerning dipole moments and their applications reference can be made to the afore-mentioned work, Volume II.

Each moment value given is that which is to be found when a group listed in the first column is attached to one of the groups listed across the top of the table. For example, the moment listed for C_6H_5-Cl is that of chlorobenzene.

Group	C_6H_5-		CH_3-		C_2H_5-		Degrees Angle

INDEX OF REFRACTION

The index of refraction of air, 1.000294, is so near unity that it is commonly used as a more convenient standard than vacuum. After measurement of the index of a substance in any medium, as air, its index in a vacuum may be computed, being equal to the index as obtained by measurement multiplied by the index (measured in a vacuum) of the medium used.

Index of refraction varies inversely with the wave length of light employed, being greater for violet than for red light. This variation is known as *dispersion* and is greater (in general) for liquids than for solids. The yellow light of sodium (*D*) is commonly employed as an approximate mean value for all parts of white light. Other wave lengths which have been used in determinations of refractive index are those corresponding to certain spectrum lines of some of the elements and are indicated by the symbols of the elements or by the letters *A'*, *C*, *D*, *E*, *F*, *G'*, and *H* which are the Fraunhofer designations. The wave lengths most commonly employed are:

Ca	= (*H*)	= 3968Å	= 396.8$m\mu$ = 0.3968 × 10^{-4}cm.
Hγ	= (*G'*)	= 4340Å	= 434.0$m\mu$ = 0.4340 × 10^{-4}cm.
Hβ	= (*F*)	= 4861Å	= 486.1$m\mu$ = 0.4861 × 10^{-4}cm.
Tl	=	= 5350Å	= 535.0$m\mu$ = 0.5350 × 10^{-4}cm.
Hg	=	= 5791Å	= 579.1$m\mu$ = 0.5791 × 10^{-4}cm.
He	= (*E*)	= 5876Å	= 587.6$m\mu$ = 0.5876 × 10^{-4}cm.
Na	= (*D*)	= 5893Å	= 589.3$m\mu$ = 0.5893 × 10^{-4}cm.
Hα	= (*C*)	= 6563Å	= 656.3$m\mu$ = 0.6563 × 10^{-4}cm.
Li	= (*Red*)	= 6708Å	= 670.8$m\mu$ = 0.6708 × 10^{-4}cm.
A	=	= 7594Å	= 759.4$m\mu$ = 0.7594 × 10^{-4}cm.
Kα	= (*A'*)	= 7699Å	= 769.9$m\mu$ = 0.7699 × 10^{-4}cm.

The index of refraction is lowered by raising the temperature. This thermal variation of index is considerable in many liquids and negligible (affecting only the 4th or 5th decimal place) in crystals. Pressure plays a noticeable role only with gases.

Optically all substances may be classified as follows:

- Isotropic Group
  - Liquids
  - Isometric system solids
- Anisotropic Group
  - Uniaxial
    - Tetragonal — Positive or Negative
    - Hexagonal — Positive or Negative
  - Biaxial
    - Orthorhombic — Positive or Negative
    - Monoclinic — Positive or Negative
    - Triclinic — Positive or Negative

ISOTROPIC GROUP (SOLIDS*)

Isotropic substances transmit light with equal velocity in all directions (isoaxial) and include gas, liquid, amorphous materials such as resins and glasses, and isometric crystals. In the table below most of the substances are isometric; a considerable number are amorphous and therefore rather variable and indefinite in their chemical composition and all their properties; a few, which are included also in their proper birefracting group, are birefracting, but their birefringence is so weak or uncertain as to make them easily mistaken for isotropic substances.

Arrangement. The substances are arranged in the order of increasing values of refractive index.

*Low temp. phase. High temp. phase is uniaxial positive.

Simple methods for determining refractive index are described by West: *Science* **101**, 283 (1945); *Chemist Analyst* **34**, 76 (1945); *ibid.* **35**, 4 and 28 (1946).

INDEX OF REFRACTION

ANISOTROPIC GROUP—UNIAXIAL

Uniaxial crystals have two refractive indices, one of the rays vibrating parallel to the optic axis and another at right angles to this direction. The ordinary ray is indicated by the symbol ω and the extraordinary ray by the symbol ϵ. If $\epsilon > \omega$ in a uniaxial substance, the substance is optically positive; if the reverse is true, negative. Uniaxial crystals may be considered simply as a small group of biaxials in which β is equal to α for a positive crystal, and to γ for a negative one.

The greater part of the substances of this group are tetragonal or hexagonal, but some that are strictly biaxial but with nearly zero axial angle are included here as well as in their proper biaxial group. A considerable proportion of these biaxial substances with nearly uniaxial optical properties have also nearly hexagonal form.

Arrangement. The substances are listed in the order of increasing values of the ω index.

Abbreviations. Hex., hexagonal; Tetr., tetragonal; Trig., trigonal; Rhomb., rhombohedral.

INDEX OF REFRACTION

ANISOTROPIC GROUP—BIAXIAL

Biaxial crystals have three refractive indices, two lying in one plane and the third in another plane of the particle. These indices are indicated by α, β, γ for the least, intermediate and the greatest index respectively of the substance. If $\gamma-\beta>\beta-\alpha$ the crystal is optically positive; if the reverse is true, negative. The indices α, β, γ have directions of vibration X, Y, Z respectively.

The greater part of the substances of this group are chiefly orthorhombic, monoclinic or triclinic.

Arrangement. The substances are listed in the order of increasing values of the β index.

Abbreviations. Ax. pl., axial plane; *a*, front and rear crystal axis; *b*, right and left crystal axis; *c*, vertical crystal axis; Lg., large; Mon., monoclinic; Mod., moderate; Ortho., orthorhombic; *r*, red light; $r>v$ (or $r<v$) signifies that the optic axial angle in red light is greater than (or less than) the optic axial angle in violet light; Sm., small; Tric., triclinic; $2V$, the true axial angle between the optic axes; X, Y, and Z, the vibration directions of the fastest, the intermediate, and the slowest ray respectively; $\wedge$, angle, for example $Z \wedge c$ is the angle between Z and c; 100, 010, 110, etc., the Miller symbols of crystal faces and forms; $=$, to indicate parallel, for example $X=a$ signifies X parallel to a; $\perp$, perpendicular. In monoclinic crystals the extinction angle is commonly measured from the vertical axis c to X, Y, or Z; if this angle lies in the obtuse angle β it is considered positive (+), but if this angle is in the acute angle β between a and c, it is negative (−).

INDEX OF REFRACTION (LIQUIDS)

Arrangement. The substances are arranged in alphabetical order. No substance is listed more than once. To ascertain if a compound is listed in the table it is to be looked for under the alphabetical listing according to its common name or by reference to an accompanying *formula index*. In using the table for the identification of an unknown liquid, reference should be made to the table *Refractive Index Finding Numbers* and in this case consideration must be given to the effect of temperature. When possible, values for the refractive index were selected at or near 20°C. The index of refraction of a liquid decreases with rise in temperature and this thermal variation differs with various substances but is approximately 0.0004 per 1°C.

Specific Gravity. As an aid in applying formulas for calculation of refractive index (*q. v.*) the specific gravity is given at the same temperature as used in the refractive index determination.

Beil. Ref. In the column so headed will be found the reference to the volume and page numbers of the 4th edition of Beilstein: *Handbuch der Organischen Chemie.* Where the Roman numeral, which indicates the volume number, is preceded by an asterisk, reference is to the first supplementary volumes; two asterisks, to the second supplementary volumes.

It is to be noted that the symbols α, β, γ which are often employed in reporting refractive index of liquids, refer to the wave length of light used and signify the wave length corresponding to the Hα, Hβ and Hγ spectrum lines. In the case of refractive index of biaxial crystals the symbols α, β and γ have a different significance (*q. v.*).

References. The information in the table has been collected mainly from the following sources:

Beilstein: *Handbuch der Organischen Chemie*, 4th edition. Published by Springer, Berlin.

International Critical Tables, Vol. VII. Published by McGraw-Hill Book Co., New York.

U. S. Bureau of Standards: *American Petroleum Institute Research Project 44.*

FORMULA INDEX

For finding compounds listed in the table: *INDEX OF REFRACTION (LIQUIDS)*

The system used in this formula index is essentially the same as that employed in *Richter's Lexikon der Kohlenstoff Verbindungen*. The succession of the element combined with carbon is as follows: H, O, N, S, F, Cl, Br, I. All the other elements are placed in alphabetical order. The arrangement depends (1) on the number of carbon atoms, (2) on the number of the other elements which, in addition to carbon are contained in the compounds, (3) on the kind of elements, which in addition to carbon are contained in the molecule, in accordance with the order as stated above and (4) on the number of atoms of each element which, in addition to carbon, is contained in the compound. Thus 2 III means two carbon atoms combined with three other elements; *e. g.*, $C_2H_2O_2F_2$ 728, is a compound with 2 carbon atoms and 3 other elements, and it is the 728th compound in the table to which this formula index is a part.

REFRACTIVE INDEX OF LIQUIDS FINDING NUMBERS

The compounds below are arranged in the order of ascending values of refractive index, an arrangement intended to serve as an aid in the identification of liquids. The numbers listed under the bold faced refractive index heading refer to the compounds with corresponding numerical listings in the table *Index of Refraction—Liquids*. Thus, under the refractive index 1.360 is listed *No. 1181* which is *ethyl isocyanide, n 1.36*.

REFRACTIVE INDEX OF AQUEOUS ALCOHOL SOLUTIONS

The table below gives the readings of the Zeiss Immersion Refractomer for various concentrations of ethyl alcohol in water. The values were calculated by B. H. St. John from the data of Doroshevskii and Dvorzhanchik. Reprinted by permission from the Official and Tentative Methods of Analysis, 3d Edition (1930), published by The Association of Official Agricultural Chemists at Washington, D. C.

CONVERSION OF SCALE DIVISIONS OF THE IMMERSION REFRACTOMETER TO REFRACTIVE INDEX

Originally the immersion instrument was designed with a single prism (*A*) of crown glass which allowed only the range from n_D 1.32 to 1.36 to be covered. By a choice of glass and prism angle it has been found possible with a battery of six prisms to extend the upper limit of the range to 1.54. Each prism of the series overlaps the one immediately above so that there is no lost region from 1.32 to 1.54. The ranges covered by these prisms are: *A*–1.32539 to 1.36674; *B*–1.36428 to 1.40608; *C*–1.39860 to 1.43830; *D*–1.43620 to 1.47562; *E*–1.47320 to 1.51335; *F*–1.50969 to 1.54409. Prism *A* is the standard to which the values in the table below apply. For the other prisms (*B* to *F*) the index of refraction is not standardized as between different manufacturers nor for different lots issued by the same manufacturer. For these prisms (*B* to *F*) it is necessary to use the table supplied with any particular instrument and impossible to publish any conversion tables which would be universally applicable.

Example: Scale division 25.1 on prism *A* corresponds to the refractive index $n_D = 1.33705 + 0.000038 = 1.33709$.

INDEX OF REFRACTION CALCULATIONS

For Organic Liquids.

Reference: Smiles, *The Relation between Chemical Constitution and some Physical Properties* (1910). Published by Longmans, Green and Co., London.

In the Lorentz and Lorenz formula:

$$\frac{n^2-1}{n^2+2}\times\frac{1}{d}=k$$

n is the index of refraction of a liquid at a given temperature, d is the density of the substance at the same temperature, and k, which is nearly independent of the temperature, is a constant known as the *specific refraction*. The product $M\times k$, where M is the molecular weight of the substance, is the *molecular refraction;* this quantity (Mk) is additive and can be calculated for most organic liquid compounds from empirically deduced atomic and structural refractive constants. Such refractive constants (k) for sodium (D) light are given in the following table:

	k		k
C	2.418	N	^{12}2.45; ^{23}21; ^{32}.65; ^{43}.59; ^{53}.00; ^{64}36; ^{72}.48; ^{82}.47; ^{93}.05; ^{103}.79; ^{113}.93; ^{122}.65; ^{132}.27; ^{142}.71; ^{153}.776; ^{163}.901; ^{174}.10; ^{183}.46
H	1.100		
O	(*a*) 1.525; (*b*) 2.211; (*c*) 1.643; (*d*) 1.64		
S	(*e*) 7.69; (*f*) 7.97; (*g*) 7.91; (*h*)8.11	NO_2	^{197}.59; ^{207}.44; ^{216}.72; ^{227}.30; ^{237}.51
Se	(*i*) 11.17		
Hal.	(*j*) 0.95; (*k*) 1.1; (*m*) 5.967; (*n*) 8 865; (*p*) 13 900	NO	^{245}.91; ^{255}.37
Str.	(*q*) 1.733; (*r*) 2.398; (*s*) 0.71; (*t*) 0.48		

In the form of: (a) (OH); (b) C:O; (c) ether OR; (d) ester OR; (e) SH; (f) RSR; (g) RCNS; (h) RSSR; (i) in dialkyl selenides; (j) one F on carbon; F (k) in polyfluorides; (m) Cl; (n) Br; (p) I; (q) double bond; (r) triple bond; (s) 3-membd. ring; (t) 4-membd. ring, (1) aliph. prim. amine; (2) arom. prim. amine; (3) aliph. sec. amine; (4) arom. sec. amine; (5) aliph. tert. amine; (6) arom. tert. amine, (7) hydroxylamine; (8) hydrazine; (9) aliph. cyanide; (10) arom. cyanide; (11) aliph. oxime; (12) prim. amide; (13) sec. amide; (14) tert. amide; (15) imidine; (16) oximido, (17) carbimido; (18) hydrazone; (19) alkyl nitrate; (20) alkyl nitrite; (21) nitro paraffin; (22) nitro arom.; (23) nitramine; (24) nitrite, (25) nitrosoamine.

Example: Allylacetic acid (CH_2:CH·CH_2·CH_2·CO·OH) has the following observed constants: $n_D^{7.5}$ = 1.4341; $d_4^{7.5}$ = 0.9903; molecular weight = 100.114. From this the calculated value of Mk is found as follows:

5 C	12.090
8 H	8.800
1 O′	1.525
1 O″	2.211
1 =	1.733
Mk_D	26.359

The observed value of Mk as calculated from the Lorentz and Lorenz formula is:

$$100.114\times\frac{(1.4341)^2-1}{(1.4341)^2+2}\times\frac{1}{0.9903}=26.330$$

Optical exaltation is characteristic of substances containing conjugated double bonds (single bonds alternating with double bonds); *i.e.*, their molecular refractions (Mk) are usually one or more units in excess of the calculated values.

For Minerals.

Reference: Larsen and Berman, *The Microscopic Determination of the Nonopaque Minerals*, 2d edition (1934); U. S. Geological Survey, Bull. 848. Washington, D. C.

In the Gladstone and Dale formula:

$$\frac{n-1}{d}=K,\ and\ K=k_1\frac{p_1}{100}+k_2\frac{p_2}{100}+etc.,$$

n is the mean index of refraction, d is the density, K is the specific refractive energy, k_1, k_2, etc. are the specific refractive energies of the components, and p_1, p_2, etc. the weight percentages of the components of a mineral. The mean index of refraction is $\frac{2\omega+\epsilon}{3}$ or $\frac{\alpha+\beta+\gamma}{3}$ unless the substance is highly birefringent when the mean index is better expressed by $\sqrt[3]{\omega^2\epsilon}$ or $\sqrt[3]{\alpha\beta\gamma}$. The specific refractive energies of the chief constituents of minerals are given in the following table:

	Molecular weight	k		Molecular weight	k
H_2O	18	[a]0.3355, [b]0.340, [c].354	As_2O_3	198	[g]0.202, [h]0.225

	Atomic weight	k		**Atomic weight**	k
H	1	1.256 or 1.44	S	32	[k]0.502, [m]1.00
C	12	.403	Cl	35.5	.303
O	16	.203	Br	80	.214
F	19	.043	I	127	.226

[a] Water and ice.
[b] Average.
[c] Alums, etc.
[d] Calculated from compounds containing the oxide.
[e] Calculated from the oxide.
[f] Calculated from feldspar, feldspathoids, etc.
[g] Isometric oxide.
[h] Monoclinic oxide.
[i] Orthorhombic oxide.
[k] Calculated from native sulfur.
[m] Calculated from sulfides; values vary.

Example: Sodium tetraborate, $Na_2B_4O_7 \cdot 5H_2O$, has the following observed constants: formula, $Na_2O \cdot 2B_2O_3 \cdot 5H_2O$; molecular weight, 292; contains, 21.2% Na_2O; 48% B_2O_3; 30.8% H_2O; d, 1.815; $\omega = 1.461$; $\epsilon = 1.474$. From the table k for Na_2O, 0.181; k for B_2O_3, 0.220; k for H_2O, 0.340. Therefore, $K = 0.181 \times 21.2\% + 0.220 \times 48\% + 0.340 \times 30.8\% = 0.24869$. Substituting in the Gladstone Dale formula:

$$\frac{n-1}{1.815} = 0.24869, \text{ or } n = 1.4514 \text{ by calculation.}$$

$$\text{The observed average value of } n = \frac{2\omega+\epsilon}{3} = \frac{2(1.461)+1.474}{3} = 1.465$$

LIQUID STANDARDS FOR REFRACTIVE INDEX DETERMINATIONS BY IMMERSION METHODS

The following compounds with the refractive indices as listed below can be obtained from the Organic Chemicals Department, Eastman Kodak Co., Rochester, N. Y. They are available in 25cc glass-stoppered bottles but only in lots of ten or more liquids.

$n^{20°}D$	Liquid
1.3289	Methyl alcohol
1.3330	Water
1.3585	Acetone
1.3725	Ethyl acetate
1.3875	*n*-Heptane
1.3986	*n*-Butyl alcohol
1.4015	*n*-Butyl chloride
1.4221	Dioxan (1,4)
1.4225	Methylcyclohexane
1.4314	Ethylene glycol
1.4420	Ethyl citrate
1.4440	Ethylene chloride
1.4480	Trimethylene chloride
1.4500	Cyclohexanone
1.4663	Cyclohexanol
1.4770	Diethanolamine
1.4847	Triethanolamine
1.4900	*p*-Cymene
1.4940	*s*-Tetrachloroethane
1.4950	Toluene
1.5005	Benzene

$n^{20°}D$	Liquid
1.5130	Ethyl iodide
1.5165	Anisole
1.5235	Trimethylene bromide
1.5246	Chlorobenzene
1.5300	Methyl iodide
1.5380	Ethylene bromide
1.5465	*o*-Nitrotoluene
1.5520	Nitrobenzene
1.5600	Tri-*o*-cresyl phosphate
1.5598	Bromobenzene
1.5720	*o*-Toluidine
1.5859	Aniline
1.5960	Bromoform
1.6090	*o*-Iodotoluene
1.6200	Iodobenzene
1.6235	Quinoline
1.6377	*s*-Tetrabromoethane
1.6578	α-Bromonaphthalene
1.6965	Phosphorus tribromide
1.7400	Methylene iodide

Crystal Type	Crystal Units	Type of Binding	Characteristic Properties: Optical
Ionic	Simple and complex ions	Electrical attraction between ions of opposite signs	Transparent; color if present is due to ions
Silicate	O^{--} or F^{-} ions; Si^{4+} or Be^{2+} or Al^{3+} and other positive ions	Weak to moderate polarization	Refractivity due to positive ions
Homopolar	Atoms of the fourth group and of groups equidistant on either side of it	Homopolar bonds throughout or strongly polarized ionic bindings	Transparent with high refractivity or opaque metalloidal
Molecular	Inert gas atoms. Non-polar and polar molecules	Van der Waal's forces or residual electric fields	Transparent. Optical properites due to molecules
Layer	Strongly polarizing and easily polarized ions	In layers, homopolar or polarized ionic. Between layers, molecular	As homopolar
Metallic	Positive ions and electron gas	Electrical attraction between positive ions and electron gas	Opaque (due to free electrons)
Metalloidal	Metal atoms and atoms of the sulfur and arsenic groups	Mixture of homopolar, ionic, and metallic binding	Opaque, metallic or transparent with high refractivity and color

OF CRYSTALS

Freshmen," by C. W. Stillwell; *Jour. Chem. Education*, 10, 598 (1933).

Characteristic Properties			
Electrical	Thermal	Mechanical	Typical Crystals
Moderate insulators; in high fields conduct by transfer of ions	Fairly high melting point; ionization occurs in liquid, vapor	Strength increasing with higher ionization and decrease in distance beweeen ions. Fracture by cleavage	NaCl, CaF_2 $CaCO_3$, K_2SO_4, $(NH_4)_2PtCl_6$
When polarization is slight, dissolve in ionizing solvents (water); when stronger, are insoluble	Very high melting points, glasses formed on cooling of melt	Very hard with tendency to cleave or fracture conchoidally	Olivine, Mg_2SiO_2; Cyanite, Al_2SiO_5; Garnet, $R^{II}_3R^{III}_2$, Si_3O_{12}; Spinel, Al_2MgO_4, Al_2O_3, SiO_2
Diamond is a perfect insulator. The others conduct metalloidally. Very insoluble	Very high melting points with tendency to vaporize except in more metalloidal	Very hard. Hardness less for metalloidal types	Diamond, Zinc Blende, ZnS; Wurtzite, ZnS; Carborundum, CSi. Many intermediate compounds— γ brass
Insulators except when very polar; soluble in non-ionizing (molecular) solvents	Melting point very low with neutral atoms	Very soft, hardness increasing with polarity of molecules	Argon, A; CO_2; Ice, H_2O; Paraffins, C_nH_{2n+2}; Cellulose
Various, similar to both molecular and homopolar	Various, similar to both molecular and homopolar	Cleaving readily in layers which are soft and flexible	Graphite, C; CdI_2
Conductors, conductivity inversely proportional to number of free electrons	Moderate to very high melting points. Long liquid interval	Moderate hardness increased by alloying	Copper, iron, sodium, zinc
Medium to bad conductors. Soluble only with decomposition	Tendency to vaporize or decompose at high temperatures	Moderately hard to soft. Properties a mixture of those of other types	NiAs, FeS, FeS_2

TOTAL MASS ABSORPTION VALUES FROM FORMULA

The values given in the following table make it possible to calculate the mass absorption for any wave length in the given range by substituting in the formula in column 3. The values are those of Richtmyer.

Absorption material	Wave length, λ, in Å	Total mass absorption μ/ρ
Al	0.1 to 0.4	$14.45\lambda^3+0.15$
Al	0.4 to 0.7	$14.30\lambda^3+0.16$
Fe	0.1 to 0.3	$110\lambda^3 + 0.18$
Co	0.1 to 0.3	$124\lambda^3+0.18$
Ni	0.1 to 0.3	$145\lambda^3+0.20$
Cu	0.1 to 0.3	$153\lambda^3+0.20$
Cu	0.1 to 0.6	$147\lambda^3+0.5$
Mo	0.1 to 0.35	$450\lambda^3+0.4$
Mo	$>\lambda_K$	$51.5\lambda^3+1$
Ag	0.1 to 0.4	$603\lambda^3+0.7$
Ag	$>\lambda_K$	$86\lambda^3+0.6$
Pb	$>\lambda_K$	$510\lambda^3+0.75$

TOTAL MASS ABSORPTION COEFFICIENTS

In the following table, the wave length, λ, is in Angstrom units, ρ is the density as given for each element in the line above the table, while μ/ρ is the total mass absorption coefficient.

CARBON. Atomic No. = 6. Density of diamond = 3.51; of graphite = 2.3

LUMINESCENCE

Luminescence is the visible radiation other than that resulting from incandescence which a material emits as a result of having been subjected to some form of energy. Emissions in the ultra-violet and the near infra-red are in general included due to the similarity of the processes leading to an emission, and due to the relatively narrow portion of the energy spectrum occupied by the three regions.

The phenomenon of luminescence is divided into *fluorescence* (the emission which occurs during excitation) and *phosphorescence* (the emission which continues after removal or extinction of the source of excitation). An artifically prepared luminescent material is called a *luminophor*, although the word *phosphor* is generally and acceptably used.

The mechanism of fluorescence is far from being fully understood. It does, however, depend upon (*1*) the absorption of energy leading to the excitation of an electron, followed by (2) the emission of energy as light when the excited electron returns to its normal unexcited state. When the excited electron is in some way retarded before or during its return, the result is *phosphorescence*. The source of the exciting energy might be 2537Å (Hg) or 3650Å (Hg) ultra-violet radiation, visible light, cathode rays, accelerated ions, X-rays, sub-atomic particles, or, in some cases, other forms of energy such as heat, friction, or chemical reaction.

Many naturally-occuring minerals and organic materials are luminescent but by far the most efficient luminescent substances are the man-made phosphors. Inorganic phosphors are usually prepared by solid-state reactions at high temperatures between compounds of extremely high purity. Often, for optimum efficiency, firing is carried out in a special atmosphere which may be reducing, oxidizing, or inert. The phosphor is composed of a base material or matrix in which has been incorporated a suitable activator in low concentrations. There are, however, a few examples of efficient phosphors which require no intentionally added activator and where the luminescence is attributed to one of the matrix elements. In certain cases a flux or mineralizing agent is required to promote the formation of a phosphor during the reaction.

A few organic substances are luminescent in the solid state; many are luminescent if dissolved in low concentrations in an appropriate solvent such as water, alcohol, or a plastic.

The applications for luminescent substances are numerous and ever-increasing. Organic phosphors find a variety of uses in chemical analyses, as tracers in detecting imperfections and flaws on the surfaces of cast parts, in spectacular display signs, and in many luminescent fabrics and plastics. Of the inorganic phosphors, the sulfide type and certain oxide types are used in cathode ray tube screens. Those possessing phosphorescence to a marked degree are used in radar screens. Extremely short phosphorescence or persistence is required for television screens. A mixture of phosphors emitting in the blue and in the yellow regions is used in black-and-white television; separate phosphors fluorescing in the blue, green, and red regions are used for color television. The oxide type phosphors are employed in fluorescent lamps where the exciting energy is primarily 2537Å (Hg) ultra-violet radiation. Other special applications for inorganic phosphors are X-ray intensification screens, image tubes, electron microscopes, scintillation counters, electroluminescent panels, and instrument dials. Each special use takes advantage of the unique characteristics of individual phosphors.

The subject is extensively treated in the following books:

H. W. Leverenz, *An Introduction to the Luminescence of Solids*, Wiley, New York, 1950; P. Pringsheim, *Fluorescence and Phosphorescence*, Interscience Publishers, New York, 1949: G. F. J. Garlick, *Luminescent Materials*, Clarendon Press, Oxford, 1949; G. R. Fonda and F. Seitz (editors), *Preparation and Characteristics of Solid Luminescent Materials*, Cornell Symposium, Wiley, New York, 1948; F. A. Kroger, *Luminescence of Solids*, Elsevier, New York, 1948; Jack DeMent, *Fluorochemistry*, Chemical Publishing Co., Brooklyn, N. Y.

PHOSPHORS

The following tables include some representative inorganic and organic phosphors. In the table of inorganic phosphors, in the column headed "phosphor" is given the chemical symbolism of the phosphor. Here the matrix precedes the colon; the activator element(s) follow. In "self-activated" phosphors, the activator is shown enclosed in brackets. In the column headed "ingredients," weight proportions are given for the sulfide-type phosphors, and molar proportions are given for the oxide-type phosphors. Under "color" is given the visual impression produced by each phosphor. Peak wavelengths of emission in angstrom units are given in the right hand column with minor peaks enclosed in parentheses. Under "Sources of excitation" are given those which are most efficient.

Abbreviations: bl-blue; dk-dark; gn-green; lt-light; med-medium; or-orange; wh-white; yel-yellow; u.v.-ultra-voilet; CR-cathode ray; L-3650Å (Hg) ultra-violet radiation; S-2537Å (Hg) ultra-violet radiation; V-visible light, usually blue or blue-green; X-x-rays. The letter *P* under "Emission peak" denotes a marked phosphorescence. The organic phosphors are excited by ultra-violet or, in some cases, by visible light.

SPECIFIC GRAVITY OF AIR AT VARIOUS TEMPERATURES

The table below gives the weight in grams $\times 10^4$ of one milliliter of air at 760 mm of mercury pressure and at the temperature indicated. Density in grams per milliliter is the same as the specific gravity referred to water at 4°C. as unity. To convert to density referred to air at 70°F. as unity, divide the values below by 12.00.

t°C.	Sp.Gr. $\times 10^4$	t°C.	Sp.Gr. $\times 10^4$	t°C.	Sp.Gr. $\times 10^4$	t°C.	Sp.Gr. $\times 10^4$

RELATIVE HUMIDITY TABLES

For Use with Hygrometer

Reprinted by Permission of The Taylor Instrument Companies, Rochester, N. Y.

The following tables are computed from data supplied by the U. S. Bureau of Standards, and are correct at a barometric pressure of 29.92 inches or 760 mm. of mercury. The values above 140° dry-bulb are extrapolated. Complete tables covering barometric pressures may be obtained by applying to the Superintendent of Documents, Government Printing Office, Washington, D. C. for psychrometric tables WB No. 235.

Use of Tables.—Locate at either the top or bottom margin the reading corresponding to the dry-bulb indication. Locate at either side margin the reading corresponding to wet-bulb indication. At the intersection of these two columns can be read the relative humidity. For example—given dry-bulb temperature 144°F. and wet-bulb temperature 112° F., relative humidity is 36%.

Precautions.—When the wick of an hygrometer becomes hard the bulb will not be thoroughly wet and inaccurate readings will result. Care should be taken to keep the wick clean. It should not be handled unless the fingers are perfectly clean, and the water should be pure and soft; distilled water is preferable. If the wick surrounding the bulb becomes hard (which can be easily detected by feeling of it) it should be discarded and replaced by a new one.

Accurate Readings.—Accuracy with fixed position hygrometers can be obtained only by creating free circulation around the bulb. When taking observations, fan the bulb vigorously for a full minute or more, then immediately take the reading.

Use of Sling Psychrometer.—Saturate the wicking covering the bulb with water at room temperature, then whirl the instrument for 15 or 20 seconds, holding it away from the body. Stop and note the indication of wet-bulb thermometer; then repeat the operation until two or more readings agree at the lowest indication obtainable. The wicking must be kept perfectly clean and thoroughly saturated to secure accurate indication.

Humidity Below the Freezing Point.—At temperatures below freezing apply water to the bare wet bulb sparingly, a thin coat of ice will then be formed on the bulb, and evaporation from the frozen surface will go on as before. In the case of desk-type and wall-type hygrometers the capillary effect of the wicking is lost when frozen so that water will have to be applied directly to the bare bulb.

These values are correct for air velocity of not less than 600 ft. per minute. The values above 140° (Dry Bulb) are extrapolated.

DRY BULB TEMPERATURE °F
WET BULB TEMPERATURE °F
1419

SOLUTIONS FOR MAINTAINING CONSTANT HUMIDITY

A saturated aqueous solution in contact with an excess of a definite solid phase at a given temperature will maintain constant humidity in an enclosed space. The table below gives a number of salts suitable for this purpose listed in order of decreasing humidity. The aqueous tension of a solution at a given temperature divided by the vapor pressure of pure water at the same temperature is equal to the relative humidity. In the following table the relative humidity is expressed in per cent and the aqueous tension of the saturated solution in mm of mercury pressure. Values in the table are from *International Critical Tables*, 1, 67; Stokes and Robinson, *Ind. Eng. Chem.*, 41, 2013 (1949); Carr and Harris, *ibid.*, 41, 2014 (1949).

EFFICIENCY OF DRYING AGENTS

Weight of Residual Water per Liter of Gas Dried at 25°C.

Drying agent	Milligrams of water
P_2O_5	2×10^{-5}
BaO	1×10^{-4}
$Mg(ClO_4)_2$	5×10^{-4}
KOH (fused)	2×10^{-3}
H_2SO_4	3×10^{-3}
$CaSO_4$	4×10^{-3}
$CaCl_2$ (granular)	0.14 – 0.25

VAPOR PRESSURES OF VARIOUS SUBSTANCES

The values in the following table were selected from the following sources from which additional data on some compounds not listed here may be found: *International Critical Tables*, vol. 3, pp 199–246; Landolt-Bornstein *Physikalish-Chemische Tabellen*, 5th ed., vol. 2, pp 1332–1381; Stull, *Ind. Eng. Chem.*, 39, 517 (1947); Rossini et al., *Selected Values of Properties of Hydrocarbons and Related Compounds*, Am. Petroleum Inst. Research Project 44; Dreisbach, *Dow Physical Property Sheets*.

For a set of tables listing the numerical values of the constants *A*, *B*, and *C* in the Antoine equation for innumerable compounds belonging to 23 classes of organic compounds (hydrocarbons, alcohols, aldehydes, ketones, acids, esters, amines, etc.) see Dreisbach's *P-V-T Relationships of Organic Compounds*, published by Handbook Publishers, Inc., Sandusky, Ohio, U. S. A. (1952). This compilation can be used also to estimate vapor pressure data for those organic compounds for which there are no published data. This book of tables, which has been in constant use in the laboratories and plants of The Dow Chemical Co., will be of value wherever vapor pressure-temperature data are needed.

For most of the compounds in the following table, values are given for the constants *A*, *B*, and *C* for use in the Antoine equation which is:

$$\text{(Equation 1)} \qquad \log_{10} P = A - B/(C + t)$$

where *P* is the vapor pressure of the compound in mm of mercury and where *t* is the temperature in degrees centigrade.

For the other compounds in the following table, values for the constants *B* and *C* are given for use in the equation:

$$\text{(Equation 2)} \qquad \log_{10} P = \frac{-52.23\,B}{T} + C$$

where *P* is the vapor pressure of the compound in mm of mercury and where *T* is the absolute temperature (t°C + 273.1).

Name	Formula	Range, °C	A	B	C

DENSITY OF MOIST AIR

The density of moist air depends upon the temperature, the humidity, and the barometric pressure. It is expressed by the equation:

$$d_t = D_t \times \frac{P - 0.3783e}{760}$$

where d_t is the density of the moist air at the temperature t; D_t is the density of dry air at the temperature t (see the table *Specific Gravity of Air*); P is the height of the barometer after correction and reduction to standard conditions, and is expressed in millimeters of mercury (see the section on *Barometry*); e is the vapor pressure of water at the temperature of the dew point and is expressed in millimeters of mercury (see the table *Vapor Pressure of Water*).

Example. To find the density of moist air at a temperature of 20°C, with a dew point of 10°C, and a corrected barometric pressure of 750 mm.

Reference to the table of *Specific Gravity of Air* shows that D at 20°C is equal to 0.0012046 g/ml. Reference to the table of *Vapor Pressure of Water* shows that at 10°C (the temperature of the dew point) e is equal to 9.209 mm. Therefore,

$$d = 0.0012046 \times \frac{750 - (0.3783 \times 9.209)}{760}$$

$$d = 0.0011832 \text{ g/ml} = 1.1832 \text{ g/l}$$

VAPOR PRESSURE OF MERCURY

PROPERTIES OF SATURATED AMMONIA

Heat Content Above −40°F. Entropy From −40°F.

U. S. Bureau of Standards, Circ. 142, 1923.

To convert: lb/ft³ to kg/m³ multiply by 16.018
ft³/lb to m³/kg multiply by 0.062426
lb/in.² to kg/cm² multiply by 0.070307
btu/lb to gcal/g multiply by 0.5556
thermochemical calory to int. joule multiply by 4.1833
absolute pressures above 14.71 lb/in.² to gage pressures lb/in.², subtract 14.71

VAPOR PRESSURE OF WATER IN MILLIMETERS OF MERCURY

For Temperatures from −10° to 118°C

The values in the table below are for water in contact with its own vapor. Where the water is in contact with air at a temperature t°C, the following correction must be added: Correction for temperatures up to 40°C $= p(0.0775 - 3.13 \times 10^{-4} t)/100$; for temperatures above 50°C $= p(0.0652 - 8.75 \times 10^{-5} t)/100$.

See also Steam Table.

VAPOR PRESSURE OF ICE IN MILLIMETERS OF MERCURY

For Temperatures from −99° to 0°C

The values in the table below are for ice in contact with its own vapor. Where the ice is in contact with air at a temperature t°C, the following correction must be added: Correction $= 20p/100\,(t+273)$.

t°C.	p mm Hg	t°C.	p mm Hg	t°C.	p mm Hg

PROPERTIES OF

METRIC AND

The values given in the table below are based upon the values given in Keenan's Steam Tables. (Copyright 1930 by The American Society of Mechanical Engineers, by permission.) The B. T. U. is 778.57 ft.-lb. (=J) which is 1/180 of the change in total heat along the saturated liquid line between 32°F. and 212° F. as determined by Osborne, Fiock and Stimson at the Bu. of Standards. The P. C. U. is 1.8 B. T. U. The values given in kg-calories/kilogram have been computed from the values in B. T. U. per pound by means of the conversion factor 0.5556. The heat of vaporization h_{fg} is the heat required to vaporize unit mass of water at the indicated temperature and

Temperature Degrees Fahrenheit.	Pressure: Pounds per square inch.	Pressure: Kilograms per square centimeter.	Pressure: Millimeters of mercury.	Heat: Of the liquid: B.T.U. per pound. SATURATED STEAM

ENGLISH UNITS

pressure. Total heat involved is $H=h_{fg}+h_f$. The external work is pv and the corresponding amount of heat is $144\ pv/J$. The heat equivalent of internal work is $u_{fg}=h_{fg}-144\ pv/J$. The values in kilograms per square centimeter and in millimeters of mercury have been computed from the values in pounds per square inch by means of the conversion factors 0.070307 and 51.715 respectively. The values in cubic meters per kilogram have been computed from the values in cubic feet per pound by means of the factor 0.062428. The densities are the reciprocals of the corresponding specific volumes.

Temperature Degrees Fahrenheit.	Heat equivalent of external work. 144 pv/J		Entropy of the liquid.	Entropy of vaporization.	Saturated vapor: Specific volume		Saturated vapor: Density		Temperature Degrees Centigrade.
	B.T.U. per pound.	Calories per kilogram.			Cubic feet per pound.	Cubic meters per kilogram.	Pounds per cubic foot.	Kilograms per cubic meter.

BOILING POINT OF WATER AT VARIOUS PRESSURES

The table below gives the boiling point of water in degrees Centigrade at various pressures in millimeters of mercury at 0°C.

See also Steam Table.

Pressure	Tenths of a millimeter of Hg									
mm of Hg	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9

CORRECTION OF BOILING POINT TEMPERATURE AT VARIOUS PRESSURES TO NORMAL PRESSURE (760 mm. Hg)

To correct for small differences in barometric pressure the following formula is employed:

$$T_c = T_o + C(760 - P_{mm})^*$$

where T_c = corrected boiling point.
T_o = observed boiling point.
P = atmospheric pressure in millimeters of mercury.
C = a constant having the value of 0.037 at 25 – 40°C; 0.043 at 41 – 75°C; 0.044 at 76 – 100°C; 0.046 at 101 – 120°C; 0.048 at 121 – 140°C; 0.051 at 141 – 155°C; 0.055 at 156 – 220°C; 0.057 at 221 – 300°C; 0.064 at 310 – 325°C.

A. S. T. M. METHOD

In the *A. S. T. M. Standards on Petroleum Products and Lubricants*, September 1937, page 96, the Sydney Young equation is used for calculating the proper correction to the observed boiling point. In this equation the temperature range as well as the pressure is considered. The Sydney Young equation is as follows:

$$\text{For Centigrade scale: } C_c = 0.00012\ (760 - P)\ (273 + t_c),$$
$$\text{For Fahrenheit scale: } C_f = 0.00012\ (760 - P)\ (460 + t_f).$$

in which C_c and C_f are, respectively, corrections to be made on the observed temperatures t_c or t_f, and P is the actual barometric pressure in millimeters of mercury.

The table which follows is a convenient approximation of the corrections as calculated from the equations above. These approximations will suffice for ordinary work. For more precise work, the correction should be calculated using the Sydney Young equation and the temperature when 50% of the material has boiled. A new correction should be made for each variation of more than 10°C. or 18°F.

As pointed out by Hoyt, *Jour. Chem. Ed.* 11, *405 (1934)*, the Sydney Young equation is applicable only to non-polar substances with low dielectric constants such as the hydrocarbons for which it was proposed by the *A. S. T. M.* For other types of compounds a more exact value can be obtained by use of the following equations and constants:

$$\text{For Centigrade scale: } C_c = K\ (760 - P)\ (273 + t_c),$$
$$\text{For Fahrenheit scale: } C_f = K\ (760 - P)\ (460 + t_f),$$

where the value of the constant K is for:

Hydrocarbons	0.000125	Esters	0.000121
Halogen derivatives	0.000125	Ketones	0.000121
Ethers	0.000125	Amines	0.000118
Aldehydes	0.000125	Alcohols	0.000100

The variation in the case of acids is too wide to permit of a single value for K.

* This formula is applicable only to liquids of particular types such as a hydrocarbon, an ether, an aldehyde, a ketone, an ester, or a halogen derivative.

(*Continued on following page.*)

CORRECTION OF BOILING POINT TEMPERATURES

Boiling Point		Correction for Each One mm. Difference in Pressure*	
t_c in °C.	t_f in °F.	C_c in °C.	C_f in °F.

350–370	662–698	.076	.137
370–390	698–734	.078	.141
390–410	734–770	.081	.145

* To be added in case barometric pressure is below 760 mm., to be subtracted in case the pressure is above 760 mm.

DREISBACH METHOD

A formula (2) has been developed from the Antoine equation (*1*) which gives the rate of change of boiling point with pressure:

$$(1)\ \log p = A - [B \div (t°C + 230)]$$
$$(2)\ dt/dp = B \div [2.3026p(A - \log p)^2]$$

This equation will give an accurate value for dt/dp at any pressure but cannot be used to correct boiling points at various barometric readings to boiling points at 760 mm pressure since the dt/dp value varies with pressure. For equations to correct for these variations and for the numerical values of the constants A and B for innumerable compounds belonging to 23 classes of organic compounds (hydrocarbons, alcohols, aldehydes, ketones, acids, esters, amines, etc.) see Dreisbach's *P-V-T RELATIONSHIPS OF ORGANIC COMPOUNDS*, published by Handbook Publishers, Inc., Sandusky, Ohio, U. S. A. (1952).

The use of this book of tables is simple and does not involve complicated mathematical operations. All of the computations have been done by the author. Its use involves merely the reading of temperature values in the body of the table corresponding to pressure values, ranging from 760 mm to 0.1 mm, which are shown across the top of the page. Values for latent heats of vaporization, vapor and liquid densities, index of refraction and flash points are also given.

This book of tables, which has been in constant use in the laboratories and plants of The Dow Chemical Co., will be of value wherever such data are required for not only compounds for which data are recorded in the literature but also for those compounds for which experimental values have not as yet been determined.

CALCULATION OF BOILING POINTS OF ORGANIC COMPOUNDS

Cf. Kinney, *Jour. Am. Chem. Soc. 60, 3032 (1938); Ind. Eng. Chem. 32, 559 (1940).*

Boiling points of organic compounds may be calculated from their structures as follows: Obtain the molecular *B.P.N.* by adding together the appropriate boiling point numbers (*b.p.n.*) for the various atoms and structural groupings given in Table I. From the *B.P.N.* obtain the B.P. (boiling point in degrees Centigrade) using Table II.

Certain rules must be followed in applying the data:

1. The *b.p.n.'s* of 0.8 and 1.0 are applied to the carbon and hydrogen atoms, respectively, of the longest aliphatic chain in the molecule. It is essential that the longest aliphatic chain be used as the base because the boiling point is dependent, in part, upon this factor.
2. All groups or atoms attached to this chain are assigned *b.p.n.'s* as indicated in Table I.
3. With many atoms and groups the position of the group, or the presence of other groups, alte the *b.p.n.* These, as far as are known, are given in Table I.

Example: To calculate the boiling point of 1-methyl-4-(1-methylethyl)-1-cyclopentene, $(CH_3)_2CH\cdot CH\cdot CH_2\cdot C(CH_3):CH\cdot CH_2$.

Carbon in the longest aliphatic chain (2 × 0.8)	1.6
Hydrogen in the longest aliphatic chain (4 × 1.0)	4.0
Methyl radical attached to the aliphatic chain	3.05
Carbon in the cyclopentene ring (5 × 0.8)	4.0
Hydrogen in the cyclopentene ring (6 × 1.0)	6.0
B.P.N. for the 5-membered ring	2.5
B.P.N. for the ethylenic linkage, type $R_2C{:}CHR$	2.3
Methyl attached to the cyclopentene ring	3.05
Calculated *B.P.N.*, sum of the items above	26.50
Calculated B.P., from Table II	142.5°C.
Observed B.P.	143.1°C.

Example: To calculate the boiling point of 2,8-dimethyl-5-nonanone, $[(CH_3)_2CH\cdot CH_2\cdot CH_2]_2CO$.

Carbon in the longest aliphatic chain (9 × 0.8)	7.2
Hydrogen in the longest aliphatic chain (16 × 1.0)	16.0
Two methyl radicals (2 × 3.05)	6.1
One carbonyl oxygen, type RCH_2COCH_2R	7.5
Calculated *B.P.N.*, sum of the items above	36 8
Calculated B.P., from Table II	222.5°C.
Observed B.P.	226.0°C.

TABLE I.

ATOMIC AND GROUP BOILING POINT NUMBERS.

Carbon, in the main chain	0.8
Hydrogen, attached to the main chain	1.0
Radicals, saturated, attached to the main chain or to cyclic rings	
Methyl	3.05
Ethyl	5.5
Propyl	7.0
Butyl	9.7
2,2-Dimethyl grouping	−0.4
Two or three alkyls attached to adjacent carbons of saturated main chains of 6 carbons or less	+0.5
Four or more alkyls attached to adjacent carbons of saturated main chains of 6 carbons or less	+1.0
Type of olefinic linkage	
$CH_2{=}CH_2$	1.2
$RCH{=}CH_2$	1.5
$RCH{=}CHR$	1.9
$R_2C{=}CHR$	2.3
$R_2C{=}CR_2$	2.8
Radicals, unsaturated, attached to main chain	
Methylene	4.4
Ethylidene	7.0
Vinyl	5.4
Propylidene	9.0
Butylidene	10.4
Type of acetylenic linkage	
$HC{\equiv}CH$	4.0
$RC{\equiv}CH$	4.4
$RC{\equiv}CCH_3$	5.4
$RC{\equiv}CR$	4.8

ATOMIC AND GROUP BOILING POINT NUMBERS (Continued)

Type of diolefin	
Allenes	4.8
Conjugated, normal values of double bonds plus	0.8
Not conjugated, normal values of double bonds only	
Type of triolefin	
All bonds conjugated, normal values of double bonds plus	2.4
Two bonds conjugated, normal values of double bonds plus	0.8
No conjugation, normal values of double bonds only	
Type of diacetylene	
1,3-Diacetylenes, normal values of triple bonds only	
All other conjugated, normal values of triple bonds plus	3.0
No conjugation, normal values of triple bonds only	
Type of enyne	
Conjugated, normal values of bonds plus	0.8
No conjugation, normal values of bonds only	
Type of dienyne	
Conjugated, normal values of bonds plus	2.4
No conjugation, normal values of bonds only	
Cyclic radicals: Add 0.8 for each carbon, 1.0 for each hydrogen, the normal values of any unsaturated linkages, and the following values for the ring:	
Cyclo-propyl, -butyl, -pentyl, -hexyl, respectively	2.1, 2.3, 2.5, 2.7
Cyclo-heptyl, -octyl, etc., (add 0.5 for each additional CH_2 in the ring)	3.4, 3.9, etc.
Alcohol —OH	
RCH_2OH	10.8
R_2CHOH	8.8
R_3COH	6.8
Ether —O—	
RCH_2OCH_3, R_2CHOCH_3, R_3COCH_3	2.9
RCH_2OCH_2R, R_2CHOCH_2R, R_3COCH_2R	2.0
$R_2CHOCHR_2$, R_3COCHR_2	1.1
R_3COCR_3	(0.2?)
Aldehyde =O	
RCH_2CHO	8.2
R_2CHCHO	7.6
R_3CCHO	7.0
Ketone =O	
RCH_2COCH_3	8.0
$R_2CHCOCH_3$, RCH_2COCH_2R	7.5
R_3CCOCH_3, $R_2CHCOCH_2R$	7.0
R_3CCOCH_2R, $R_2CHCOCHR_2$	6.5
R_3CCOCH_2R	(6.0?)
R_3CCOCR_3	(5.5?)
Ester —OO—	
RCH_2COOCH_3, CH_3COOCH_2R	8.5
$R_2CHCOOCH_3$, RCH_2COOCH_2R, $HCOOCHR_2$, $CH_3COOCHR_2$	7.6
$R_3CCOOCH_3$, $R_2CHCOOCH_2R$, $RCH_2COOCHR_2$, $HCOOCR_3$, CH_3COOCR_3	6.7
$R_3CCOOCH_2R$, $R_2CHCOOCHR_2$, RCH_2COOCR_3	5.8
$R_3CCOOCHR_2$, $R_2CHCOOCR_3$	4.9
$R_3CCOOCR_3$	4.0
Acid —COOH	
RCH_2COOH	19.3
$R_2CHCOOH$	18.6
R_3CCOOH	17.9
Amine, primary $—NH_2$	
RCH_2NH_2	7.3
R_2CHNH_2	6.2
R_3CNH_2	5.1
Amine, secondary —NH—	
RCH_2NHCH_3	5.0
$R_2CHNHCH_3$, RCH_2NHCH_2R	4.0
R_3CNHCH_3, $R_2CHNHCH_2R$	3.5
R_3CNHCH_2R, $R_2CHNHCHR_2$	3.0
Amine, tertiary =N—	
$RCH_2N(CH_3)_2$	2.0
$R_2CHN(CH_3)_2$, $(RCH_2)_2NCH_3$	1.5
$R_3CN(CH_3)_2$, $(R_2CH)_2NCH_3$, $(RCH_2)_3N$	1.25
Cyanide —CN	
RCH_2CN	14.0
R_2CHCN	12.8
R_3CCN	11.6
Isocyanide —NC	
RCH_2NC	12.2
R_2CHNC	11.1
R_3CNC	10.0

TABLE II.

MOLECULAR BOILING POINT NUMBERS AND THEIR BOILING POINTS.

Calculated from the formula: $B.P. = 230.14\sqrt[3]{B.P.N.} - 543$

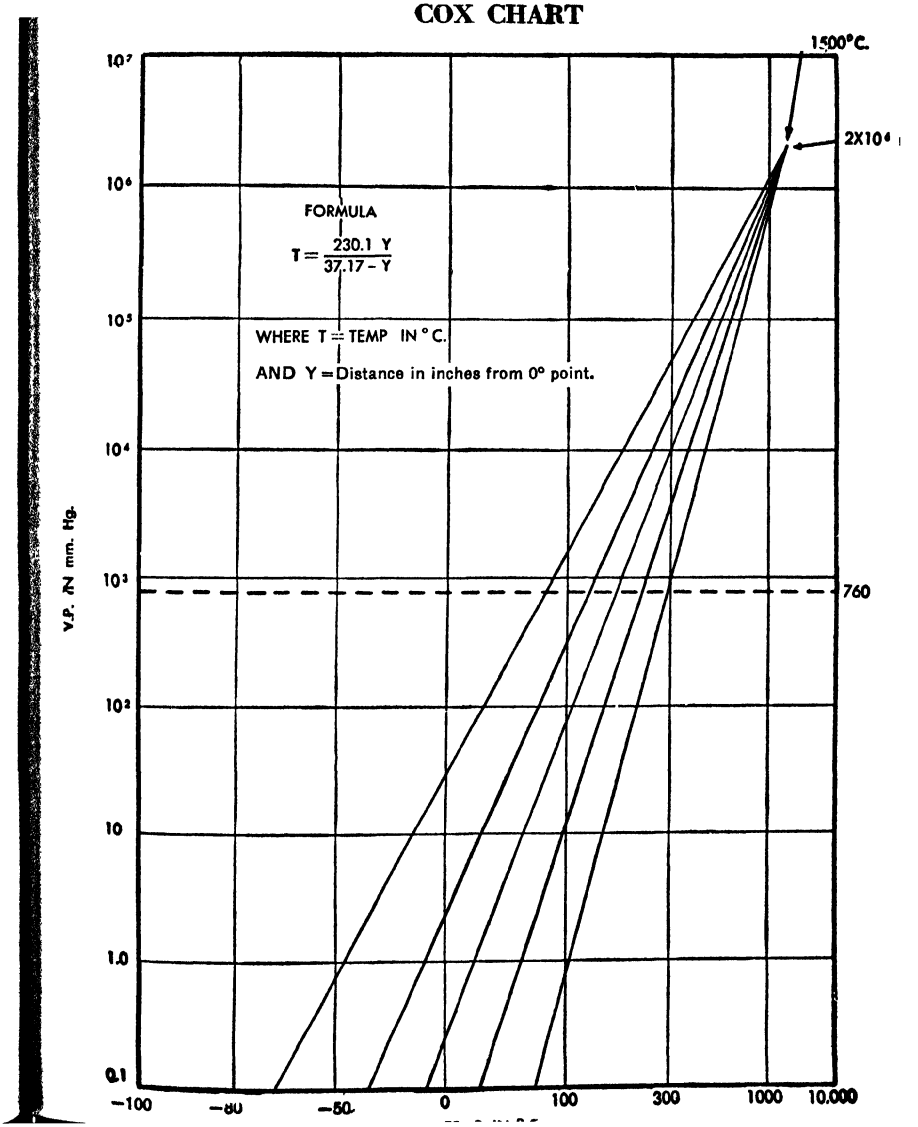
BOILING POINTS AT VARIOUS PRESSURES
COX CHART METHOD

Cf. Cox, *Ind. Eng. Chem. 15, 592 (1923)*; Davis, *ibid. 17, 735 (1925)*; Calingaert and Davis, *ibid. 17, 1287 (1925)*.



A Cox chart, of the family to which a compound belongs, may be used to obtain the boiling point at any pressure, or the vapor pressure at any temperature. By drawing a straight line through the boiling point at 760 mm. and the infinite point, a curve is obtained which gives the relationship between the temperature and the vapor pressure. To construct a Cox chart, the ordinates for pressure values are laid off logarithmically with the aid of a log scale on a slide rule. The formula $T = 230.1Y \div (37.17 - Y)$ is used for spacing of the temperature values on the abscissa. Drawn in this manner, a Cox chart can be applied to any family of compounds or to any single compound. The sample chart shown on the following page shows curves for the vapor pressures of five compounds belonging to the alkyl benzene family with the infinite point at 1500°C. and 2×10^6mm. The five curves are representative of five compounds with normal boiling points at 80°, 110°, 210°, 260°, and 290°C. respectively. A size of chart which is satisfactory is 56 inches high and 38.75 inches wide with pressures from 0.1 mm. to 10^7mm. The values of T cover the range from −100°C. to +10,000°C., the 0° point being 17.25 inches from the left side or −100° point of the chart.

Some compounds, *e.g.*, the amyl alcohols, do not come within the family where they should belong. In general, aromatic compounds seem to lie in families on the Cox chart to a much greater degree than do aliphatic compounds.

COX CHART FAMILY	Infinite Point	
	°C.	10^6mm. Hg
(1) ***Aliphatic hydrocarbons*** The series C_nH_{2n+2}; also pinene, camphene, and limonene	1240	1.3
(2) ***Aliphatic halides*** Mono- and poly-halogen derivatives of the series C_nH_{2n+2} and C_nH_{2n}, except acetylene tetrachloride	1390	1.43
(3) ***Aliphatic alcohols and ketones*** The lower members of the alcohol series $C_nH_{2n+2}O$ and $C_nH_{2n}O$. The saturated ketones of the series $C_nH_{2n}O$; unsaturated ketones apparently are exceptions	610	1.5
(4) ***Aliphatic acids and esters*** The saturated acids of the series $C_nH_{2n}O_2$ where $n<7$, and the esters $C_nH_{2n}O_2$ where $n<6$	520	0.24
(5) ***Aliphatic esters*** The saturated esters of the series $C_nH_{2n}O_2$ where $n>5$; also acetoacetic ester; *iso*-butyl oxalate; benzyl, linalyl, bornyl, and menthyl acetates; bornyl propionate and *n*-butyrate; methyl, ethyl, *n*-propyl, and *iso*-butyl benzoates; methyl salicylate	1100	1.1
(6) ***Aliphatic acids*** The saturated acids of the series $C_nH_{2n}O_2$ where $n>6$ and the unsaturated acids of the series $C_nH_{2n-2}O_2$ from $n=4$ to $n=11$; also chloroacetic and benzoic acids	1100	4.2
(7) ***Alkyl benzenes*** The series C_nH_{2n-6}, C_nH_{2n-8}, and their ring halogen derivatives	1500	2.0
(8) ***Phenols*** The series $C_nH_{2n-6}O$ and *m*-chlorophenol	1900	9.0
(9) ***Aromatic alcohols*** The series $C_nH_{2n-6}O$ and their ring halogen derivatives	3300	20.0
(10) ***Anilines*** The series $C_nH_{2n-5}N$ and their ring halogen derivatives; also benzylamine	1300	2.3

COX CHART FAMILY (Continued)	Infinite Point	
	°C.	10^6mm. Hg
(11) *Naphthalenes*		
The series C_nH_{2n-12} and their ring halogen derivatives; the alkyl naphthalenes, their unsaturated derivatives, and their ring halogen compounds	1320	1.0
(12) *N-alkyl primary amines*		
The series $C_nH_{2n+2}N$	1125	14.0
(13) *The nitro paraffins*		
The series $C_nH_{2n+1}NO_2$	1350	20.0

COX CHART

AZEOTROPIC MIXTURES

These tables give the data for various binary and ternary azeotropic or constant boiling mixtures.

For a very complete listing of azeotropes see Horsley, *Ind. Eng. Chem., Analytical Edition, 19, 508 (1947)*.

For a thorough discussion of Azeotropy, see Lecat, *Traite de Chimie Organique*, V. Grignard, Mason et Cie, Paris, 1935, Tome I, pp. 121 to 267; or Young, *Distillation Principles and Processes*, Macmillan, London, 1922.

The boiling points listed are in °C. at 760 mm.

These data are taken from Lecat, "*L'Azeotropisme*", Brussels, 1918; *Ann. soc. sci. Bruxelles 45B, 169–76, 284–94 (1926)*; *47B, i, 21–7, 63–71, 108–14, 149–58 (1927)*; *48B, i, 13–22, 54–62, 113–26; ii, 1–18 (1928)*; *49B, ii, 17–47, 109–43 (1929)*; *50B, 21–33 (1930)*; *55B, 43–7, 253–65 (1935)*; *56B, 41–54, 221–34 (1936)*; *Rec. trav. chim. Pays-Bas 45, 620–7 (1926)*; *46, 240–7 (1927)*; *47, 13–18 (1928)*, unless otherwise designated as follows:

CRITICAL CONSTANTS OF GASES

See also values for critical points given in the table: *Orthobaric Densities or Volumes of Various Substances.*

The values in the following table were selected from various sources but mostly from "The Critical Properties of Elements and Compounds," by Kobe and Lynn, *Chem. Reviews*, **52**, 117 (1953) with changes as recommended in a private communication from Kobe. For a set of tables which may be used to estimate critical constants of many organic compounds for which there are no published data, see Dreisbach's *P-V-T Relationships of Organic Compounds*, published by Handbook Publishers, Inc., Sandusky, Ohio, U. S. A. (1952). This book of tables, which has been in constant use in the laboratories and plants of The Dow Chemical Co., will be of value wherever data on critical constants are needed.

HEAT CAPACITY STANDARDS

In the following tables for water, mercury, and aluminum oxide the units of temperature are based on the International Temperature Scale of 1948 using 0°C = 273.16°K. Values expressed in calories are in units of the "defined" calorie. This calorie which is independent of the properties of water is by definition equal to 4.1833 international joules. Redefined in January 1948 this calorie is equal to 4.1840 absolute joules. One absolute joule = 0.999835 international joule = 0.239006 calorie.

WATER

The values in the following table were determined by Ginnings and Furukawa of the National Bureau of Standards. Published in the *J. Am. Chem. Soc.*, 75, 522 (1953), they are reproduced here by permission of the American Chemical Society. For international use in calorimetry, the International Committee on Weights and Measures has approved a heat capacity table (Procès-Verbaux of the International Committee on Weights and Measures, Session of 1950, p. 92) which differs from this table by less than 0.005 joule per degree per gram mole.

Values in the columns headed *C-satd.* and *C-p* give the heat capacities (specific heats) at saturation pressure and at 1 atmosphere (760 mm Hg) pressure, respectively. The units in the columns headed *J* are in absolute joules per degree per gram mole (mol. wt. = 18.016); the units in the columns headed *cal.* are in calories per degree per gram.

MERCURY

The values in the following table were determined by Douglas, Ball and Ginnings, and published in *J. Research Natl. Bur. Standards*, 46, 334 (1951). Values in the columns headed *C-satd.*, *C-p*, and *C-v* are those for liquid-vapor equilibrium, maintenance of constant pressure, and maintenance of constant volume, respectively. The units are in "defined calories." (1 calorie = 4.1840 absolute joules = 4.1833 international joules.)

ALUMINUM OXIDE

The values in the following table were determined by Ginnings and Furukawa of the National Bureau of Standards on aluminum oxide in the form of synthetic sapphire (corundum) in pieces that passed a #10 and were retained by a #40 sieve and with impurities between 0.01 and 0.02% by weight Heat capacity values below the experimental range were obtained by extrapolating a Debye equation fitted to the experimental values at the lowest temperature. The units in the columns headed *J* are in absolute joules per degree per gram mole (mol. wt. = 101.96) at constant pressure of 1 atmosphere (760 mm Hg); the units in the columns headed *cal.* are in calories per degree per gram at constant pressure of 1 atmosphere. Published in the *J. Am. Chem. Soc.*, 75, 522 (1953), they are reproduced here by permission of the American Chemical Society.

HEATS OF SOLUTION

The values given in this table are expressed in kilo-calories per gram mole of compound as shown by the formula and for a dilution as indicated (where this is not indicated the dilution is such that further dilution is without an appreciable, thermal effect); a positive value indicates an evolution of heat during solution. To convert from kilogram calories to B. T. U. multiply by the factor 3.9685.

VAN DER WAALS' CONSTANTS FOR GASES

Calculated from the values given in *Landolt-Bornstein Phys.-Chem. Tab.*, 5th Ed., p. 254 (1923); published by J. Springer, Berlin.

$$\left(P + \frac{a}{V^2}\right)\left(V - b\right) = RT \text{ for } \textit{one} \text{ mole}$$

To use the values of a and b in the table below, P must be expressed in atmospheres and V in liters per mole; then $R = 0.08207$ liter atmospheres per mole per degree; T is degrees absolute.

$$\left(P + \frac{n^2a}{V^2}\right)\left(V - nb\right) = nRT \text{ for } n \text{ moles}$$

Name	Formula	a $\frac{(\text{liters})^2 \times \text{atm.}}{(\text{mole})^2}$	b $\frac{\text{liters}}{\text{mole}}$

KOPP'S RULE

This rule, which should be used only where experimental values are lacking, states that the specific heat of a compound is approximately equal to the sum of the heat capacities of the constituent elements and that an *approximate* value expressed in gram calories per gram formula weight can be calculated by assigning the following atomic heat capacities to the elements:

For solids: C, 1.8; H, 2.3; O, 4.0; S, 5.4; P, 5.4; F, 5.0; Si, 3.8; B, 2.7; all other elements, 6.2.

For liquids: C, 2.8; H, 4.8; O, 6.0, S, 7.4; P, 7.4; F, 7.0; Si, 5.8; B, 4.7; all other elements, 8.0.

Example. For $BaCO_3$: $6.2 + 1.8 + (3 \times 4.0) = 20.0$ g cal/g formula weight; or, $20.0 \div 197.37 = 0.1013$ g cal/g. Found by experiment, 0.0999.

SPECIFIC HEAT OF ELEMENTS, COMPOUNDS AND VARIOUS SUBSTANCES*

The values are given in gram-calories (15°) per gram per degree Centigrade. To convert to joules per gram per degree Centigrade multiply by 4.185.

*Value for solid state at −10°C.

THERMAL CONDUCTIVITY

In the following tables dealing with heat conductivity, the coefficient λ is given in g.-cal./(sec.)(sq. cm.)(°C./cm.). This is the quantity of heat in gram calories, transmitted per second through a plate of the material one centimeter thick and one square centimeter in area when the temperature difference between the two sides of the plate is one degree Centigrade. To express λ in English units, btu./(sec.)(sq. in.)-(°F./inch), multiply the values given below by 0.00560.

HEAT OF FUSION OF INORGANIC COMPOUNDS

Most of the values in the following table are from the tables of *Selected Values of Chemical Thermodynamic Properties of the National Bureau of Standards* by Rossini *et al.*, Am. Petroleum Inst., Project 44, Carnegie Inst. of Tech.

For elements see special table.

The heat of fusion (ΔH) is given in gram-calories (15°) per gram. To convert to: (*a*) joules (abs) per gram multiply by 4.185; (*b*) joules (int) per gram multiply by 4.183; (*c*) btu per pound multiply by 1.8.

Name	Formula	*t*, °C	ΔH
Aluminum bromide	Al_2Br_6	97.5	10.1
chloride	Al_2Cl_6	192 (1625 mm)	63.4
iodide	Al_2I_6	191	4.7
sodium fluoride	Na_3AlF_6	1000	99.1
oxide	Al_2O_3	2040	25.5
Ammonia	NH_3	−77.7 (45 6mm)	79.3
Ammonium nitrate	NH_4NO_3	169.6	16.2
sulfate, acid	NH_4HSO_4	144	29.7
Antimony bromide (tri)	$SbBr_3$	96.6	9.7
chloride (tri)	$SbCl_3$	73.4	13.3
chloride (penta)	$SbCl_5$	3.0	8.0
oxide	Sb_4O_6	655 (8 5mm)	50.6
sulfide	Sb_4S_6	547	16.5
Arsenic bromide (tri)	$AsBr_3$	31.2	8.9
chloride (tri)	$AsCl_3$	−16	13.4
fluoride (tri)	AsF_3	−6.0	18.8
fluoride (penta)	AsF_5	−80.3 (149mm)	15.9
oxide (II)	As_4O_6	274 (28mm)	30.1
oxide (I)	As_4O_6	313 (67mm)	22.2
Arsine	AsH_3	−116.3 (24 6mm)	7.2
Barium chloride	$BaCl_2$	962	25.9
fluoride	BaF_2	1320	17.1
hydroxide	$Ba(OH)_2$	408	19.8
nitrate	$Ba(NO_3)_2$	595.5	23.0
phosphate	$Ba_3(PO_4)_2$	1727	30.9
sulfate	$BaSO_4$	1350	41.6
chloride	$BiCl_3$	232	8.2
Boron fluoride	BF_3	−128.7 (54mm)	14.7
hydride	B_2H_6	−165.5	38.3
hydride	$B_{10}H_{14}$	99.5 (20 6mm)	63.8
oxide	B_2O_3	450	75.7
Cadmium bromide	$CdBr_2$	568	18.4
chloride	$CdCl_2$	568 (0 97mm)	28.9
fluoride	CdF_2	1110	35.9
iodide	CdI_2	387 (0 48mm)	21.8
nitrate	$Cd(NO_3)_2 \cdot 4H_2O$	59 5	25.3
Calcium aluminum silicate	$CaO \cdot Al_2O_3 \cdot 2SiO_2$	1550	105.7
borate	$CaO \cdot B_2O_3$	1162	140.6
borate	$CaO \cdot 2B_2O_3$	987	138.5
borate	$2CaO \cdot B_2O_3$	1312	132.5
chloride	$CaCl_2$	782	61.1
chloride	$CaCl_2 \cdot 6H_2O$	30.2	40.7
fluoride	CaF_2	1418	90.9
nitrate	$Ca(NO_3)_2$	561	31.1
nitrate	$Ca(NO_3)_2 \cdot 4H_2O$	42.6	33.9
oxide	CaO	2600	214.0
sulfate	$CaSO_4$	1400	49.2
titanate	$CaTiO_3$	1257	4.0

HEAT OF VAPORIZATION OF COMPOUNDS

For elements see special table.

The heat of vaporization (ΔHv) is given in gram-calories (15°) per gram. To convert to: (*a*) joules (abs) per gram multiply by 4.185; (*b*) joules (int) per gram multiply by 4.183; (*c*) btu per pound multiply by 1.8.

Name	Formula	*t*, °C	ΔHv
